1 **Abstract**

2 The Ensemble Transform Kalman Filter (ETKF) assimilation scheme has recently
3 seen rapid development and wide application. As a specific implementation of the
4 Ensemble Kalman Filter (EnKF), the ETKF is computationally more efficient than the
5 conventional EnKF. However, the current implementation of the ETKF still has some
6 limitations when the observation operator is strongly nonlinear. One problem in the
7 minimization of a nonlinear objective function similar to 4D-Var is that the nonlinear
8 operator and its tangent-linear operator have to be iteratively calculated if the Hessian
9 is not preconditioned or the Hessian has to be calculated several times. This may be
10 computationally expensive. Another problem is that it uses the tangent-linear
11 approximation of the observation operator to estimate the multiplicative inflation factor
12 of the forecast errors, which may not be sufficiently accurate.

13 This study attempts to solve these problems. First, we apply the second-order
14 Taylor approximation to the nonlinear observation operator in which the operator, its
15 tangent-linear operator and Hessian are calculated only once. The related
16 computational cost is also discussed. Second, we propose a scheme to estimate the
17 inflation factor when the observation operator is strongly nonlinear. Experimentation
18 with the Lorenz-96 model shows that using the second-order Taylor approximation of
19 the nonlinear observation operator leads to a reduction of the analysis error compared
20 with the traditional linear approximation method. Furthermore, the proposed inflation
21 scheme leads to a reduction of the analysis error compared with the procedure using
22 the traditional inflation scheme.

1 **1. Introduction**

2

3 The spatial and temporal distribution of observations is continuously changing
4 with the improvement of numerical models and observation techniques. Sounding data,
5 remote sensing observations, satellite radiance data and other indirect information bring
6 both opportunities and challenges in data assimilation. How to assimilate these indirect
7 observations is an important research topic in data assimilation (Reichle, 2008).

8 The observation operators for indirect observations are often nonlinear. For
9 example, radiative transfer codes (e.g., RTTOV, CRTM, Saunders et al., 1999; Han et
10 al., 2006) can be treated as observation operators by mapping air temperature and
11 moisture to the microwave radio brightness temperature (McNally, 2009). Because the
12 relationship of these observations with modelled variables may be strongly nonlinear
13 (Liou, 2002) and the observation errors may be spatially correlated (Miyoshi et al.,
14 2013), data assimilation schemes have to be appropriately designed to address such
15 indirect observations.

16 Most data assimilation methods are fundamentally based on linear theory but have
17 different responses to departures from linearity (Lawson and Hansen, 2004).
18 Conceptually, variational data assimilation schemes (VAR, e.g., Parrish and Derber,
19 1992; Courtier et al., 1994; Lorenc, 2003) can assimilate data with nonlinear
20 observation operators and spatially correlated observation errors. However, a drawback
21 of VAR is that it has to calculate the adjoint of a dynamical model, which is not an easy
22 task in practice. Moreover, VAR does not give a direct estimate of the background error

1 covariance matrix, which is crucial for the performance of any data assimilation scheme.
2 In general ensemble data assimilation, Maximum Likelihood Ensemble Filter (MLEF)
3 minimizes a cost function that depends on a general nonlinear observation operator to
4 estimate the state vector, which is equivalent to maximize the likelihood of the posterior
5 probability distribution (Zupanski, 2005). Particle filter uses a set of weighted random
6 samples (particles) to approximate the posterior probability distribution that may
7 depend on a nonlinear observation operator (Leeuwen, 2009).

8 The Ensemble Kalman Filter (EnKF) scheme has a strategy to optimize forecast
9 error statistics without using the adjoint of the dynamical model (e.g., Evensen, 1994a,
10 1994b; Burgers et al., 1998; Anderson and Anderson, 1999; Wang and Bishop, 2003;
11 Wu et al., 2013). It is also conceptually applicable to data assimilation with nonlinear
12 observation operators. However, it has been demonstrated that when the observation
13 operator is strongly nonlinear, using the linear approximation of the observation
14 operator to derive the error covariance evolution equation can result in an
15 oversimplified closure and dubious performance of the EnKF (e.g., Miller et al., 1994;
16 Evensen, 1997; Yang et al., 2012).

17 The Ensemble Transform Kalman Filter (ETKF) was first introduced in
18 atmospheric assimilation by Bishop and Toth (1999) and Bishop et al. (2001). Wang
19 and Bishop (2003) transformed the forecast perturbations into analysis perturbations by
20 multiplying a transformation matrix. They also proposed an efficient way to construct
21 the transform matrix through eigenvector decomposition of a matrix of the ensemble
22 size. Hunt et al. (2007) extended the ETKF method to deal with a general nonlinear

1 observation operator using the cost function. In addition to the reduction of
2 computational cost compared with EnKF, another advantage of the ETKF proposed by
3 Hunt et al. (2007) is that it can assimilate observations with strongly nonlinear
4 observation operators (Chen et al., 2009) and with spatially correlated observation
5 errors (Stewart et al., 2013).

6 However, there are still problems associated with the ETKF when the observation
7 operator is strongly nonlinear. First, the current ETKF is based on the minimization of a
8 cost function similar to that in VAR for nonlinear observation operators (Hunt et al.
9 2007). First, the direct calculation for the minima requires iterative evaluation of the
10 nonlinear operators and their tangent-linear operators. Using linear approximation of
11 the nonlinear observation operators (e.g. Hunt et al. 2007) can effectively reduce the
12 computational burden, but at the cost of increasing analysis error. Second,
13 tangent-linear approximation of the observation operator is used for the forecast error
14 inflation in the ETKF (e.g., Li et al., 2009). If the observation operators are strongly
15 nonlinear, the inflation factors and hence the forecast error covariance matrices may be
16 estimated erroneously, leading to an eventual increase in the analysis error.

17 In this study, we propose two alternative approaches to improving assimilation
18 quality when the observation operator is strongly nonlinear. First, in an effort to reduce
19 computational cost without significantly reducing estimation quality, we use the
20 second-order Taylor expansion of the observation operator to estimate both the inflation
21 factors and the analysis states. Second, for the case where the inflation factor is
22 constant in space, we propose a new forecast error inflation method for general

1 nonlinear observation operators without using tangent-linear approximation. It is
2 worthwhile to point out that the proposed methodology implicitly assumes the use of
3 incremental minimization with outer and inner loops. There may be other efficient
4 methods available in mathematical optimization and control theory.

5 The potential use of the second-order information has been noted by some authors.
6 For example, Hunt et al. (2007) noted that the second-order derivatives of the objective
7 function might be used to estimate the covariance of analysis weight, which is an
8 important step in ETKF with a nonlinear observation operator. Moreover, Le Dimet et
9 al. (2002) and Daescu and Navon (2007) noted that the second-order information in
10 nonlinear variational data assimilation is important to the issue of solution uniqueness.

11 In the conventional ETKF scheme, linear approximation of nonlinear observation
12 operators is used for the purpose of reducing the computational cost compared with
13 conventional methods of searching the minima of nonlinear cost functions (Hunt et al.,
14 2007). This study also aims to investigate the changes of analysis errors when a
15 nonlinear observation operator is substituted by its first-order and second-order Taylor
16 approximations. However we focus on the formulation of the forecast error inflation
17 method in the case of a nonlinear observation operator and on the improved accuracy
18 with second-order versus first-order approximation or linear approximation. Further
19 studies on the performance of the proposed schemes in practical data assimilations are
20 needed and should be performed in the future.

21 The rest of the paper is organized as follows. Our modified ETKF schemes are
22 described in Sect. 2. The assimilation results on a Lorenz-96 model with a nonlinear

1 observation system are presented in Sect. 3. The discussions are given in Sect. 4, and
2 conclusions are in Sect. 5.

3

4 **2. Methodology**

5

6 **2.1. ETKF with forecast error inflation**

7

8 Hunt et al. (2007) gave a comprehensive description of the ETKF with a nonlinear
9 observation operator without procedures for forecast error inflation. In this section, we
10 propose an inflation scheme for general nonlinear observation operators.

11 Using the notations of Ide et al. (1997), a nonlinear discrete-time forecast and
12 observation system can be written as

$$13 \quad \mathbf{x}_i^t = M_{i-1}(\mathbf{x}_{i-1}^a) + \boldsymbol{\eta}_i, \quad (1)$$

$$14 \quad \mathbf{y}_i^o = H_i(\mathbf{x}_i^t) + \boldsymbol{\varepsilon}_i, \quad (2)$$

15 where i is the time step index; $\mathbf{x}_i^t = \{X_{1,i}^t, X_{2,i}^t, \dots, X_{n,i}^t\}^T$ is the n -dimensional true state
16 vector; $\mathbf{x}_{i-1}^a = \{X_{1,i-1}^a, X_{2,i-1}^a, \dots, X_{n,i-1}^a\}^T$ is the n -dimensional analysis state vector which is
17 an estimate of \mathbf{x}_{i-1}^t ; M_i is the nonlinear forecast operator; $\mathbf{y}_i^o = \{y_{1,i}^o, y_{2,i}^o, \dots, y_{p_i,i}^o\}^T$ is
18 the p_i -dimensional observation vector; $H_i = \{h_{1,i}, h_{2,i}, \dots, h_{p_i,i}\}^T$ is the nonlinear
19 observation operator, where $h_{k,i}$ is a n -dimensional multivariate function; and $\boldsymbol{\eta}_i$ and
20 $\boldsymbol{\varepsilon}_i$ are the forecast and observation error vectors which are assumed to be statistically
21 independent of each other, time-uncorrelated, and to have mean zero and covariance
22 matrices \mathbf{P}_i and \mathbf{R}_i , respectively. The detailed procedure of the ETKF with a

1 nonlinear observation operator (Hunt et al. 2007) with the proposed inflation scheme is
 2 as follows.

3 Step 1. Calculate the j -th perturbed forecast state at time i as

$$4 \quad \mathbf{x}_{i,j}^f = M_{i-1}(\mathbf{x}_{i-1,j}^a), \quad (3)$$

5 where $\mathbf{x}_{i-1,j}^a$ is the j -th perturbed analysis state at time $i-1$. Then, the mean forecast
 6 state is defined as

$$7 \quad \mathbf{x}_i^f = \frac{1}{m} \sum_{j=1}^m \mathbf{x}_{i,j}^f, \quad (4)$$

8 where m is the total number of ensemble members.

9 Step 2. Assume the forecast errors to be in the form $\sqrt{\lambda_i}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)$,
 10 ($j=1,2,\dots,m$), where the inflation factor λ_i can be estimated by minimizing the
 11 objective function

$$12 \quad L_i(\lambda) = \text{Tr} \left[\left(\mathbf{d}_i \mathbf{d}_i^T - \mathbf{C}_i(\lambda) - \mathbf{I} \right) \left(\mathbf{d}_i \mathbf{d}_i^T - \mathbf{C}_i(\lambda) - \mathbf{I} \right)^T \right]. \quad (5)$$

13 Here, \mathbf{I} is the $p_i \times p_i$ identity matrix,

$$14 \quad \mathbf{d}_i = \mathbf{R}_i^{-1/2} \left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) \right) \quad (6)$$

15 is the innovation vector normalized by the square root of the observation error
 16 covariance matrix (Wang and Bishop, 2003), and

$$17 \quad \mathbf{C}_i(\lambda) \equiv \frac{1}{m-1} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left(H_i(\mathbf{x}_i^f + \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)) - H_i(\mathbf{x}_i^f) \right) \left(H_i(\mathbf{x}_i^f + \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)) - H_i(\mathbf{x}_i^f) \right)^T \mathbf{R}_i^{-1/2} \right]. \quad (7)$$

18 (See Appendix A for details).

19 Step 3. Calculate the analysis state as

$$20 \quad \mathbf{x}_i^a = \mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}_i^a \quad (8)$$

21 where

$$22 \quad \mathbf{X}_i^f = \left(\mathbf{x}_{i,1}^f - \mathbf{x}_i^f, \mathbf{x}_{i,2}^f - \mathbf{x}_i^f, \dots, \mathbf{x}_{i,m}^f - \mathbf{x}_i^f \right) \quad (9)$$

1 and \mathbf{w}_i^a is estimated by minimizing the objective function

$$2 \quad J_i(\mathbf{w}) = \frac{1}{2}(m-1)\mathbf{w}^T\mathbf{w} + \frac{1}{2}\left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i}\mathbf{X}_i^f\mathbf{w})\right]^T \mathbf{R}_i^{-1}\left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i}\mathbf{X}_i^f\mathbf{w})\right]. \quad (10)$$

3 Step 4. Calculate a perturbed analysis state as

$$4 \quad \mathbf{x}_{i,j}^a = \mathbf{x}_i^a + \sqrt{\hat{\lambda}_i}\mathbf{X}_i^f\mathbf{W}_{i,j}^a \quad (11)$$

5 where $\mathbf{W}_{i,j}^a$ is the j -th column of the matrix $\mathbf{W}_i^a = \sqrt{m-1}\left(\ddot{J}_{i/\mathbf{w}_i^a}\right)^{-1/2}$ and $\ddot{J}_{i/\mathbf{w}_i^a}$ is the

6 second-order derivative of $J_i(\mathbf{w})$ at \mathbf{w}_i^a (see Appendix B for details). Lastly, set

7 $i = i + 1$ and return to Step 1 for the next iteration.

8 For estimating the inflation factor, Li et al. (2009) proposed a scheme which

9 requires the tangent-linear operator of the observation operator (see Sect. 2.2.1 for the

10 definition). In an effort to reduce computational cost of searching the minima of the

11 objective function (10), Hunt et al. (2007) suggested the following linear

12 approximation,

$$13 \quad H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i}\mathbf{X}_i^f\mathbf{w}) \approx H_i(\mathbf{x}_i^f) + \mathbf{Y}_i^f\mathbf{w} \quad (12)$$

14 where

$$15 \quad \mathbf{Y}_i^f = \left(H_i(\sqrt{\hat{\lambda}_i}(\mathbf{x}_{i,1}^f - \mathbf{x}_i^f) + \mathbf{x}_i^f) - H_i(\mathbf{x}_i^f), H_i(\sqrt{\hat{\lambda}_i}(\mathbf{x}_{i,2}^f - \mathbf{x}_i^f) + \mathbf{x}_i^f) - H_i(\mathbf{x}_i^f), \right. \\ 16 \quad \left. \dots, H_i(\sqrt{\hat{\lambda}_i}(\mathbf{x}_{i,m}^f - \mathbf{x}_i^f) + \mathbf{x}_i^f) - H_i(\mathbf{x}_i^f) \right). \quad (13)$$

17 In this study, this traditional ETKF approach is validated against other approaches.

18

19 **2.2. Simplified estimation methods in special cases**

20

21 To compute the variational minimization in Eq. (10) operationally, one can directly

1 compute the explicit solution of the minima and iterate the process as in the 4D-Var
 2 outer loop (Lorenc, 2003; Liu et al., 2008). However, doing so still requires repeatedly
 3 calculating the nonlinear function $H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w})$ and its tangent-linear operator
 4 (see Sect. 2.2.1 for the definition) which depend on \mathbf{w} and \mathbf{x}_i^f . In this subsection, we
 5 propose an alternative procedure when the observation operator H_i can be
 6 approximated by its Taylor expansions.

7 2.2.1. First-order Taylor approximation for H_i

8 The first-order Taylor approximation for H_i at the forecast state vector \mathbf{x}_i^f is
 9 defined as

$$10 \quad H_i(\mathbf{x}_i^t) \approx H_i(\mathbf{x}_i^f) + \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} (\mathbf{x}_i^t - \mathbf{x}_i^f), \quad (14)$$

11 where

$$12 \quad \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} = \begin{pmatrix} \frac{\partial h_{1,i}}{\partial \mathbf{x}_{1,i}} & \dots & \frac{\partial h_{1,i}}{\partial \mathbf{x}_{n,i}} \\ \vdots & \ddots & \vdots \\ \frac{\partial h_{p_i,i}}{\partial \mathbf{x}_{1,i}} & \dots & \frac{\partial h_{p_i,i}}{\partial \mathbf{x}_{n,i}} \end{pmatrix}_{\mathbf{x}_i = \mathbf{x}_i^f} \quad (15)$$

13 is the first-order derivative of H_i evaluated at the forecast state \mathbf{x}_i^f (tangent-linear
 14 operator). Then, λ_i can be estimated by minimizing the quadratic function

$$15 \quad L_{1,i}(\lambda) = \text{Tr} \left[\left(\mathbf{d}_i \mathbf{d}_i^T - \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} - \mathbf{I} \right) \left(\mathbf{d}_i \mathbf{d}_i^T - \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} - \mathbf{I} \right)^T \right]. \quad (16)$$

16 The analytic solution is

$$17 \quad \hat{\lambda}_i = \frac{\text{Tr} \left[\mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} (\mathbf{d}_i \mathbf{d}_i^T - \mathbf{I})^T \right]}{\text{Tr} \left[\mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} \right]}, \quad (17)$$

18 where

$$\hat{\mathbf{P}}_i = \mathbf{X}_i^f (\mathbf{X}_i^f)^T / (m-1). \quad (18)$$

Similarly, \mathbf{w}_i^a can be estimated by minimizing the multivariate quadratic function

$$J_{1,i}(\mathbf{w}) = \frac{1}{2}(m-1)\mathbf{w}^T\mathbf{w} + \frac{1}{2}\left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i}\dot{\mathbf{H}}_{i|\mathbf{x}_i^f}\mathbf{X}_i^f\mathbf{w}\right]^T \mathbf{R}_i^{-1}\left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i}\dot{\mathbf{H}}_{i|\mathbf{x}_i^f}\mathbf{X}_i^f\mathbf{w}\right] \quad (19)$$

and the analytic solution is

$$\mathbf{w}_i^a = \left((m-1)\mathbf{I} + \hat{\lambda}_i(\mathbf{X}_i^f)^T \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f\right)^{-1} \sqrt{\hat{\lambda}_i}(\mathbf{X}_i^f)^T \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1}(\mathbf{y}_i^o - H_i(\mathbf{x}_i^f)). \quad (20)$$

(see Appendix C for details).

2.2.2. Second-order Taylor approximation for H_i

The second-order Taylor approximation for H_i at \mathbf{x}_i^f is defined as

$$H_i(\mathbf{x}_i^t) \approx H_i(\mathbf{x}_i^f) + \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}(\mathbf{x}_i^t - \mathbf{x}_i^f) + \frac{1}{2}\left((\mathbf{x}_i^t - \mathbf{x}_i^f)^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{x}_i^t - \mathbf{x}_i^f)\right), \quad (21)$$

where $\dot{\mathbf{H}}_{i|\mathbf{x}_i^f}$ is the tangent-linear operator defined in Eq. (15), and

$\ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \equiv \left\{ \ddot{\mathbf{H}}_{1,i|\mathbf{x}_i^f}, \dots, \ddot{\mathbf{H}}_{p_i,i|\mathbf{x}_i^f} \right\}^T$ is the second-order derivative of H_i at \mathbf{x}_i^f , which is an

p_i -dimensional vector with the k -th element meaning the following Hessian matrix:

$$\ddot{\mathbf{H}}_{k,i|\mathbf{x}_i^f} \equiv \left(\begin{array}{ccc} \frac{\partial^2 h_{k,i}}{\partial x_{1,i} \partial x_{1,i}} & \dots & \frac{\partial^2 h_{k,i}}{\partial x_{1,i} \partial x_{n,i}} \\ \vdots & \ddots & \vdots \\ \frac{\partial^2 h_{k,i}}{\partial x_{n,i} \partial x_{1,i}} & \dots & \frac{\partial^2 h_{k,i}}{\partial x_{n,i} \partial x_{n,i}} \end{array} \right)_{\mathbf{x}_i = \mathbf{x}_i^f} \quad k = 1, \dots, p_i. \quad (22)$$

Here \otimes is the outer product operator, i.e., for two arbitrary n -dimensional vectors \mathbf{x}

and \mathbf{y} ,

$$\mathbf{x}^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes \mathbf{y} = \left\{ \mathbf{x}^T \ddot{\mathbf{H}}_{1,i|\mathbf{x}_i^f} \mathbf{y}, \dots, \mathbf{x}^T \ddot{\mathbf{H}}_{p_i,i|\mathbf{x}_i^f} \mathbf{y} \right\}^T, \quad (23)$$

is a p_i -dimensional vector. Then, λ_i can be estimated by minimizing the polynomial

objective function of $\lambda^{1/2}$

$$L_{2,i}(\lambda) = \text{Tr} \left[\left(\mathbf{d}_i \mathbf{d}_i^T - \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} - \lambda^{3/2} \mathbf{C}_{1,i} - \lambda^{3/2} \mathbf{C}_{1,i}^T - \lambda^2 \mathbf{C}_{2,i} - \mathbf{I} \right) \right]$$

$$1 \quad \left(\mathbf{d}_i \mathbf{d}_i^T - \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} - \lambda^{3/2} \mathbf{C}_{1,i} - \lambda^{3/2} \mathbf{C}_{1,i}^T - \lambda^2 \mathbf{C}_{2,i} - \mathbf{I} \right)^T, \quad (24)$$

2 where

$$3 \quad \mathbf{C}_{1,i} = \frac{1}{2(m-1)} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \sqrt{\hat{\lambda}_i} (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) \left((\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) \right)^T \mathbf{R}_i^{-1/2} \right], \quad (25)$$

4 and

$$5 \quad \mathbf{C}_{2,i} = \frac{1}{4(m-1)} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left((\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) \right) \left((\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) \right)^T \mathbf{R}_i^{-1/2} \right], \quad (26)$$

6 are two $m \times m$ matrices.

7 Moreover, \mathbf{w}_i^a can be estimated by minimizing the multivariate polynomial objective

8 function

$$9 \quad J_{2,i}(\mathbf{w}) \approx \frac{1}{2} (m-1) \mathbf{w}^T \mathbf{w} + \frac{1}{2} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} - \frac{\hat{\lambda}_i}{2} \left((\mathbf{X}_i^f \mathbf{w})^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{X}_i^f \mathbf{w}) \right) \right]^T$$

$$10 \quad \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} - \frac{\hat{\lambda}_i}{2} \left((\mathbf{X}_i^f \mathbf{w})^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{X}_i^f \mathbf{w}) \right) \right] \quad (27)$$

11 (see Appendix D for details).

12

13 2.3 Validation statistics

14

15 In the following experiments, the “true” state \mathbf{x}_i^t is known by experimental

16 design and is non-dimensional. In this case, we can use the Root Mean Square Error of

17 the Analysis state (A-RMSE) to evaluate the accuracy of the assimilation results. The

18 A-RMSE at the i -th step is defined as

$$19 \quad \text{A-RMSE} = \sqrt{\frac{1}{n} \left\| \mathbf{x}_i^a - \mathbf{x}_i^t \right\|^2}, \quad (28)$$

1 where $\|\cdot\|$ denotes the Euclidean norm and n is the dimension of the state vector. A
2 smaller A-RMSE indicates a better performance of the assimilation scheme.

3 Following Anderson (2007) and Liang et al. (2012), the Root Mean Square Error
4 of the Forecast state (F-RMSE) and the Spread of the Forecast state (F-Spread) at the
5 i -th step are defined as

$$6 \quad \text{F-RMSE} = \sqrt{\frac{1}{n} \|\mathbf{x}_i^f - \mathbf{x}_i^t\|^2}. \quad (29)$$

7 and

$$8 \quad \text{F-Spread} = \sqrt{\frac{1}{n(m-1)} \sum_{j=1}^m \|\mathbf{x}_{i,j}^f - \mathbf{x}_i^f\|^2}. \quad (30)$$

9 Roughly speaking, if $\mathbf{x}_{i,j}^f$ and \mathbf{x}_i^t are identically distributed with a mean value of \mathbf{x}_i^f ,
10 then F-RMSE and F-Spread should be consistent with each other. This is more likely
11 the case if the model error is small. In general, the F-RMSE can be decomposed into an
12 F-Spread component and a model error component, so it is larger than F-Spread (see
13 Appendix B of Wu et al. (2013) for a detailed proof). Beside model error, the
14 nonlinearities and the sampling error may also affect the consistency between F-RMSE
15 and F-Spread as it is discussed later in this paper.

16

17 **3. Experiments with the Lorenz-96 model**

18

19 In Sect. 2.1, we outlined the general ETKF assimilation scheme with
20 Second-order Least Squares (SLS) error covariance matrix inflation. In Sect. 2.2, we
21 proposed simplified estimation methods for two special cases where H_i either is

1 tangent-linear (Sect. 2.2.1) or can be approximated by the second-order Taylor
2 expansion (Sect. 2.2.2). In this section, we apply these assimilation schemes to the
3 Lorenz-96 model (Lorenz, 1996) with model errors and a nonlinear observation system
4 because it is a nonlinear dynamical system with properties relevant to realistic forecast
5 problems.

6

7 **3.1. Description of the dynamic and observation system**

8

9 The Lorenz-96 model (Lorenz, 1996) is a strongly nonlinear dynamical system
10 with quadratic nonlinearity governed by the equation

$$11 \quad \frac{dX_k}{dt} = (X_{k+1} - X_{k-2})X_{k-1} - X_k + F, \quad (31)$$

12 where $k = 1, 2, \dots, K$ ($K = 40$, so there are 40 variables). We apply the cyclic
13 boundary conditions $X_{-1} = X_{K-1}, X_0 = X_K, X_{K+1} = X_1$. The dynamics of Eq. (31) are
14 “atmosphere-like” in that the three terms on the right-hand side consist of a nonlinear
15 advection-like term, a damping term and an external forcing term, respectively. These
16 terms can be thought of as a given atmospheric quantity (e.g., zonal wind speed)
17 distributed on a latitude circle.

18 We solve Eq. (31) using the fourth-order Runge-Kutta time integration scheme
19 (Butcher, 2003) with a time step of 0.05 non-dimensional units to derive the true state.
20 This is equivalent to about 6 hours in real time, assuming that the characteristic
21 time-scale of the dissipation in the atmosphere is 5 days (Lorenz, 1996). In our
22 assimilation schemes, we set $F=8$ so that the leading Lyapunov exponent implies an

1 error-doubling time of approximately 8 time steps (i.e., 0.4 non-dimensional time units)
 2 and the fractal dimension of the attractor is 27.1 (Lorenz and Emanuel, 1998). The
 3 initial condition is chosen to be $X_k = F$ when $k \neq 20$ and $X_{20} = 1.001F$.

4 Because the microwave brightness temperature is an exponential function of soil
 5 temperature, we use the exponential observation function to mimic the radiative
 6 transfer model in this study. Suppose the synthetic observation generated at the k -th
 7 model grid point is

$$8 \quad y_{k,i}^o = x_{k,i}^t \exp\{\alpha x_{k,i}^t\} + \varepsilon_{k,i}, \quad (32)$$

9 where $k = 1, \dots, p_i$, and $\varepsilon_i = \{\varepsilon_{1,i}, \varepsilon_{2,i}, \dots, \varepsilon_{p_i,i}\}^T$ is the observation error vector with
 10 mean zero and covariance matrix \mathbf{R}_i . Here, α is a parameter controlling the
 11 nonlinearity of the observation operator, and $\alpha = 0$ corresponds to the linear case. All
 12 40 model variables are observed in our experiments. Suppose the observation errors are
 13 spatially correlated. The leading-diagonal elements of \mathbf{R}_i are $\sigma_o^2 = 1$, and the
 14 off-diagonal elements at site pair (j, k) are

$$15 \quad \mathbf{R}_i(j, k) = \sigma_o^2 \times 0.5^{\min(|j-k|, 40-|j-k|)}. \quad (33)$$

16 With the exponential observation function and spatially correlated observation errors,
 17 the proposed scheme may potentially be applied to assimilate remote sensing
 18 observations and radiance data.

19 We added model errors in the Lorenz-96 model because they are inevitable in real
 20 dynamic systems. The model is a forced dissipative model with a parameter F that
 21 controls the strength of the forcing (Eq. (31)). It behaves quite differently with
 22 different values of F , and it produces chaotic systems with integer values of F larger

1 than 3. Thus, we used various values of F to simulate a wide range of model errors
2 while retaining $F=8$ when generating the “true” state. These observations were then
3 assimilated with $F=4, 5, \dots, 12$. We simulated observations every 4 time steps for
4 100,000 steps to ensure robust results (Sakov and Oke, 2008; Oke et al., 2009). The
5 ensemble size is 30.

6

7 **3.2. Assimilation results**

8

9 In this section, we examine the following five data assimilation methods
10 corresponding to five different treatments of nonlinearity in inflation factor estimation
11 and optimization:

12 ETKF: Traditional ETKF in linear approximation (Eq. (12)) and optimization (Eq.
13 (10)).

14 TT: Tangent-linear approximation in both inflation (Eq. (17)) and optimization
15 (Eq. (20))

16 TN: Tangent-linear approximation in inflation (Eq. (17)) and nonlinearity in
17 optimization (Eq. (10))

18 SS: Second-order approximation in both inflation (Eq. (24)) and optimization (Eq.
19 (27))

20 NN: Nonlinearity in both inflation (Eq. (5)) and optimization (Eq. (10)).

21 The corresponding time-mean A-RMSEs of these assimilation schemes with
22 $\alpha = 0.1$ and $F=4, 5, \dots, 12$, over 100,000 time steps are plotted in Fig. 1(a). First, the

1 figure clearly shows that for each estimation method, the A-RMSE increases as F
2 becomes increasingly distant from the true value of 8.

3 Moreover, method NN has a smaller A-RMSE uniformly over all values of F than
4 method TN, indicating that the proposed nonlinear inflation estimation (Eq. (5))
5 performs better than the tangent-linear inflation scheme (Eq. (17)). On the other hand,
6 the A-RMSEs of methods SS and TN are close and smaller than that of method TT,
7 suggesting that the second-order Taylor approximation method is comparable to the
8 partial nonlinear method and is better than the first-order Taylor approximation method.
9 Lastly, the traditional ETKF method has the largest A-RMSE, which implies that
10 although the linear approximation is computationally more efficient, it may introduce
11 larger analysis error.

12 For the Lorenz-96 model with large error ($F=12$), the time-mean A-RMSEs and
13 F-RMSEs of the five methods are given in Table 1 as well as the time-mean values of
14 the objective functions. The function represents the second-order distance of the
15 squared innovation statistic ($\mathbf{d}_i \mathbf{d}_i^T$) to its expectation. Generally speaking, for a more
16 accurate assimilation scheme, the realization of $\mathbf{d}_i \mathbf{d}_i^T$ should be closer to its
17 expectation and therefore the value of the objective function should be smaller. It can
18 be seen that the full nonlinear method (NN) has both the smallest A-RMSE and
19 F-RMSE, while the traditional linear approximation method (ETKF) has the largest
20 RMSEs. The second-order Taylor approximation method (SS) performs similarly to the
21 partial nonlinear method (TN), but better than the first-order Taylor approximation
22 method (TT). In the majority of the cases, a smaller error corresponds to a smaller

1 value of the objective function L . The ratios of F-RMSEs over A-RMSEs are also listed
2 in Table 1, which can be considered as a measurement of the improvement gained at
3 the analysis step. All the ratios are larger than 1, which indicate that the analysis state
4 is better than the forecast state. Among all methods, the ratio is largest for the method
5 TN, which indicates the largest error reduction at the analysis step.

6 To illustrate the variation of A-RMSE with respect to the parameter α , the
7 corresponding time-mean A-RMSEs of different assimilation schemes with $F=12$
8 and $\alpha=0, 0.02, 0.04, 0.06, 0.08, 0.1$ are plotted in Fig. 1(b). It shows that all the
9 schemes have the same A-RMSE with $\alpha=0$ (i.e. the observation operator is linear),
10 indicating that there is no difference among them. For each scheme, the A-RMSE
11 increases as the parameter α increases from 0 to 0.1. The magnitude relation of all
12 schemes is basically consistent with that in Fig. 1(a). The larger the parameter α is,
13 the bigger difference the different schemes have.

14 To investigate the consistency between F-RMSE and F-Spread, we present the
15 time-mean values of the five methods for cases $F=12$ and $F=8$ in Tables 2 and 3,
16 respectively, as well as the ratios of F-RMSE over F-Spread. It is easy to see that in all
17 cases, the F-RMSEs are larger than F-Spreads, and therefore, all ratios are greater than
18 1. However, the ratio of the full nonlinear method (NN) is the smallest, while the ratio
19 of the linear approximation method is the largest. The ratio of the second-order
20 approximation method (SS) is comparable to that of the partial nonlinear method (TN),
21 but smaller than that of the first-order approximation method (TT). This suggests that
22 the ensemble perturbed predictions are the most (least) reasonable for method NN

1 (ETKF). Moreover, the ratios with $F=8$ are much closer to 1 than those with $F=12$
 2 because the model error with $F=12$ is much larger than that with $F=8$ (see Sect. 2.3).

3

4 **3.3. Impacts of Taylor approximations**

5

6 In Sect. 3.2, we see that the A-RMSEs derived from the five ETKF assimilation
 7 schemes are close when F is close to the true value of 8 but are different when F
 8 departs from 8. This effect may depend on how well the Taylor expansions
 9 approximate the nonlinear observation operator H_i .

10 For example, the Taylor expansion of the k -th component of observation operator

11 $H_i(\mathbf{x}) = \mathbf{x} \exp\{\alpha \mathbf{x}\}$ (Eq. (32)) with $\alpha = 0.1$ around the forecast state $\mathbf{x}_{k,i}^f$ is

$$\begin{aligned}
 12 \quad \mathbf{x}_{k,i}^t \exp\{0.1 \mathbf{x}_{k,i}^t\} &= \mathbf{x}_{k,i}^f \exp\{0.1 \mathbf{x}_{k,i}^f\} + (1 + 0.1 \mathbf{x}_{k,i}^f) \exp\{0.1 \mathbf{x}_{k,i}^f\} (\mathbf{x}_{k,i}^t - \mathbf{x}_{k,i}^f) \\
 13 \quad &+ (0.2 + 0.01 \mathbf{x}_{k,i}^f) \exp\{0.1 \mathbf{x}_{k,i}^f\} (\mathbf{x}_{k,i}^t - \mathbf{x}_{k,i}^f)^2 + \dots. \quad (34)
 \end{aligned}$$

14 To verify how well the Taylor expansions approximate the nonlinear observation
 15 operator H_i , we calculate the ratios of the Taylor expansion residuals over
 16 $\mathbf{x}_{k,i}^t \exp\{0.1 \mathbf{x}_{k,i}^t\}$. If a ratio falls outside the interval $[-0.1, 0.1]$, then the corresponding
 17 residual cannot be regarded as being of a higher order infinitesimal and hence cannot
 18 be ignored. Therefore, a larger proportion of the ratios falling outside the interval $[-0.1,$
 19 $0.1]$ indicates a worse Taylor expansion and vice versa.

20 The proportions of the ratios that fall outside the interval $[-0.1, 0.1]$ are plotted in
 21 Fig. 2, which shows that when $F=8$, the proportions are 0.0169 and 0.0006 for the
 22 first-order and second-order Taylor expansions, respectively. This result indicates that

1 at almost all times and locations, both the first-order and second-order Taylor
2 expansions are good approximations of $x_{k,i}^t \exp\{0.1x_{k,i}^t\}$. However, when $F=12$, at
3 approximately 47% (19%) of the times and locations, $x_{k,i}^t \exp\{0.1x_{k,i}^t\}$ cannot be
4 adequately approximated by its first (second) order Taylor expansion. Therefore, the
5 A-RMSEs derived by the five ETKF schemes are quite different. This example also
6 indicates that the success of the Taylor approximation method depends on both the
7 smoothness of H_i and the range of forecast states. It seems that for the same strongly
8 nonlinear observation operator, the larger the model error, the less success of the Taylor
9 approximation.

10

11 **4. Discussions**

12

13 **4.1. Inflation**

14

15 It is widely recognized that the initial estimates of ensemble forecast errors should
16 be inflated to improve assimilated results. To date, however, all of the existing adaptive
17 inflation schemes in ETKF are based on the assumption that the observation operator is
18 linear or tangent-linear (e.g., Li et al., 2009; Miyoshi, 2011). In this study, a method to
19 estimate the multiplicative inflation factors is proposed for general nonlinear
20 observation operators.

21 Historically, in systems such as the Met Office ETKF (Flowerdew and Bowler,

22 2011), the need for inflation arises primarily due to spurious correlations that cause the

1 raw analysis ensemble to be severely under-spread even when the background
2 ensemble is well-spread. In this case, therefore, inflation must be applied to the
3 analysis ensemble to correctly respond to the actual analysis uncertainty in the
4 nonlinear forecast step. Inflation of the background ensemble may be more appropriate
5 when the inflation primarily represents forecast model error, although stochastic
6 physics or additive inflation may also be appropriate in this case (Hamill and Whitaker,
7 2005; Wu et al., 2013).

8 Our choice to inflate the background ensemble is crucial to the ability of finding a
9 direct nonlinear solution for Eqs. (5)-(7) because of the way the inflation factor appears
10 in these equations. The objective function for estimating the multiplicative inflation
11 factors is the second-order distance between the expectations of the squared innovation
12 and its realization, which also makes the rms spread equal to the rms error (e.g., Palmer
13 et al., 2006; Wang and Bishop, 2003; Flowerdew and Bowler, 2011).

14 The proposed nonlinear method is tested using the Lorenz-96 model with
15 nonlinear observation systems (Sect. 3.2). The resulting A-RMSEs are clearly smaller
16 than those of the first-order Taylor approximation in the estimation of the inflation
17 factor. This indicates that the proposed full nonlinear inflation method is better than the
18 first-order Taylor approximation inflation method in the case of nonlinear observation
19 operators (i.e., method NN is better than method TN). In addition, the F-RMSE and
20 F-Spread of the proposed nonlinear method are more consistent than those of the
21 first-order Taylor approximation method. The second-order approximation method for
22 estimating inflation factors while using the nonlinear optimization scheme is also

1 investigated. The corresponding A-RMSE is 2.20 for the forcing parameter $F=12$ and
 2 parameter of observation operator $\alpha = 0.1$, which is larger than that of method TN and
 3 smaller than that of method NN.

4 The proposed inflation methods work well in the case where observation errors
 5 are spatially correlated. Some data assimilation schemes assume the observation error
 6 covariance matrix to be diagonal for simplicity and ease of computation (e.g.,
 7 Anderson 2007, 2009). However, because satellite observations often contain
 8 significantly correlated errors, the observation error covariance matrix has nonzero
 9 off-diagonal entries (Miyoshi et al., 2013). The inflation method proposed in this study
 10 can be applied to assimilate such observations.

11 In many practical experiments, the inflation factor is constant in time and is
 12 chosen by trial and error to give the assimilation with the most favourable statistics (e.g.
 13 Anderson and Anderson 1999). For testing the fixed-tuned inflation method, suppose
 14 $\mathbf{x}_i^a(\lambda)$ and $\mathbf{x}_i^f(\lambda)$ are the analysis state and forecast state using time invariant inflation

15 factor λ . Then the statistics $\sum_{i=1}^N \sqrt{\frac{1}{P_i} \|\mathbf{y}_i^o - H_i(\mathbf{x}_i^a(\lambda))\|^2}$ and $\sum_{i=1}^N \sqrt{\frac{1}{P_i} \|\mathbf{y}_i^o - H_i(\mathbf{x}_i^f(\lambda))\|^2}$ are

16 minimized to tune the λ respectively. When Eq (10) is minimized to estimate the
 17 weights of perturbed analysis states, the corresponding A-RMSEs of the two
 18 fixed-tuned methods are estimated as 2.97 and 2.85 respectively which are larger than
 19 that of method SS (2.29). The ratios of F-RMSE to F-Spread are estimated as 3.14 and
 20 3.45 respectively which are also larger than 1.80 of method SS (see Table 1). All these
 21 facts indicate that the empirical estimation method for the inflation factor is not as
 22 good as method SS.

1

2 **4.2. Second-order Taylor approximation**

3

4 In Sect.s 3.2, we showed that the ETKF scheme equipped with our proposed
5 nonlinear inflation method leads to the smallest A-RMSE in all ETKF schemes
6 analysed in this study. However, this ETKF scheme requires repeated calculation of the
7 nonlinear observation functions $H_i(\mathbf{x}_i^f + \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f))$ and $H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w})$ when
8 minimizing the objective functions $L_i(\lambda)$ and $J_i(\mathbf{w})$. To reduce the computational
9 cost, a commonly used approach is to substitute H_i by its tangent-linear operator (i.e.,
10 first-order Taylor expansion). However, this approach comes at the cost of losing
11 estimation quality, as we have shown in this study.

12 As an effort to strike a balance between the estimation quality and computational
13 cost, the nonlinear observation operator H_i in the objective functions $L_i(\lambda)$ and
14 $J_i(\mathbf{w})$ is substituted by its second-order Taylor expansion. This is because (1) the
15 second-order Taylor expansion is a better approximation of H_i than its tangent-linear
16 operator; (2) with second-order Taylor expansion, the inflation factor λ and the
17 weight vector \mathbf{w} are concentrated out of H_i , so the objective functions (Eqs. (24) and
18 (27)) become polynomials, for which a minima is easier to derive; and (3) the
19 second-order derivative of H_i is required for estimating ensemble analysis states (Eq.
20 (11)) in the ETKF scheme, so its computation is not an additional task.

21 The accuracy of the ETKF scheme with the second-order Taylor approximation is
22 examined in Sect. 3.2. The results suggest that the scheme is more accurate than the

1 ETKF scheme based on the first-order Taylor approximation and is comparable with
2 the scheme based on nonlinear optimization and tangent-linear multiplicative inflation.
3 However, it is less accurate than the nonlinear optimization and nonlinear inflation
4 estimation ETKF scheme proposed in this study. On the other hand, both schemes have
5 similar F-RMSE over F-Spread ratios.

6 Despite the advantage that the objective functions (Eqs. (24) and (27)) are easier
7 to minimize, the computational cost of the ETKF with the second-order Taylor
8 approximation may increase from computing $(\mathbf{X}_i^f \mathbf{w})^T \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f, k} \mathbf{X}_i^f \mathbf{w}$. Because the most
9 typical nonlinear observation operator in numerical weather prediction is the radiative
10 transfer model RTTOV, the related computational issue is discussed and is documented
11 in Appendix E. In fact, unlike forecast operators, the observation operators are usually
12 localized, and therefore, the computation of $(\mathbf{X}_i^f \mathbf{w})^T \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f, k} \mathbf{X}_i^f \mathbf{w}$ is still feasible. For
13 the observation operators which are not localized, the computation of the second-order
14 term may be complex.

15 In additional, there are other ways to address this problem. For example, in the
16 deterministic variational framework, Met Office re-linearizes the observation operator
17 every 10 iterations (Rawlins et al., 2007), and ECMWF uses a nonlinear outer loop.
18 Both approaches retain the efficiency of a tangent-linear approximation in the inner
19 loop, while allowing for nonlinearity at a higher level. To better understand the efficacy
20 of the ETKF scheme with second-order Taylor approximation, a more careful
21 comparison with alternative assimilation schemes is necessary. We plan to face this
22 challenge in the near future.

1

2 **4.3. Caveats**

3

4 This study assumes the inflation factor to be constant in space, but this is
5 apparently not the case in many practical applications, specifically when observations
6 are sparse. Applying the same inflation value to all state variables may overinflate the
7 forecast errors of the state variables without observations (Hamill and Whitaker, 2005;
8 Anderson, 2009; Miyoshi et al., 2010; Miyoshi and Kunii, 2012). If the forecast model
9 has a large error, a multiplicative inflation may not be effective enough to improve the
10 assimilation results. In this case, the additive inflation and localization technique may
11 be applied to further improve the assimilation quality (Wu et al., 2013).

12 This study also assumes that the analysis increment can be expressed as a linear
13 combination of ensemble forecast errors (Eq. (8)). This assumption is true if the
14 observation operator is tangent-linear, but the nonlinear observation operator can affect
15 the combination of possible increments that produce the optimal analysis (Yang et al.,
16 2012). However, our examples demonstrate that the proposed ETKF methods can still
17 work well when the observation operators are not tangent-linear.

18 For general nonlinear or even non-smooth radiative transfer operators (Steward et
19 al. 2012), the utility of higher-order elements in Taylor expansion may be questionable.
20 Also, the development of the second order term may be time consuming and difficult
21 in case of complex observation operators, especially when the observation operators
22 cannot be localized.

1 At the last but not the least, the results concluded in this study are related to the
2 Lorenz-96 experiment and may not be regarded as general rules. However, they can
3 serve as counter examples to validate some ideas.

4 5 **5. Conclusions**

6
7 In this study, a new approach to inflating the ensemble forecast errors is proposed
8 for the ETKF with a nonlinear observation operator. For an idealized model, it is
9 shown that the proposed inflation approach can reduce analysis error compared with
10 the tangent-linear multiplicative inflation, despite it being computationally more
11 expensive. An ETKF scheme with the second-order Taylor approximation is also
12 proposed. In terms of analysis error, the scheme is better than the first-order Taylor
13 approximation ETKF scheme and traditional ETKF scheme, especially when the model
14 error is larger. However, it is comparable to the scheme based on nonlinear
15 optimization and tangent-linear multiplicative inflation. The proposed ETKF scheme
16 with nonlinear optimization and nonlinear inflation was found to be the best among all
17 schemes presented in this study. Finally, the proposed method is computationally
18 feasible to assimilate satellite observations with radiative transfer models as the
19 nonlinear observation operators (see Appendix E) which are broadly used in
20 atmospheric, ocean and land data assimilations.

21 In the future studies, we plan to further investigate the computational efficiency of
22 the proposed ETKF schemes and to validate them using more sophisticated dynamic

1 models and observation systems.

2

3 **Appendix A: Derivation of Eq. (6)**

4 The estimation of the inflation factors λ is based on the innovation statistic
5 normalized by the square root of the observation error covariance matrix

$$6 \quad \mathbf{d}_i = \mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^f)) \\ 7 \quad = \mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) + \mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)), \quad (\text{A1})$$

8 where \mathbf{y}_i^o , \mathbf{x}_i^f and \mathbf{x}_i^t are the observation, forecast and true state vector at the i -th
9 time step, respectively, and H_i is the observation operator. The mean value of $\mathbf{d}_i \mathbf{d}_i^T$ is

$$10 \quad E(\mathbf{d}_i \mathbf{d}_i^T) = E \left[\left(\mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) + \mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)) \right) \left(\mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) + \mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)) \right)^T \right]. (\text{A2})$$

11 where E is the expectation operator. Especially, if the observation operator is a linear
12 matrix (\mathbf{H}_i), Eq. (A2) can be simplified to

$$13 \quad E(\mathbf{d}_i \mathbf{d}_i^T) = \mathbf{R}_i^{-1/2} \mathbf{H}_i \hat{\mathbf{P}}_i \mathbf{H}_i^T \mathbf{R}_i^{-1/2} + \mathbf{I}, \quad (\text{A3})$$

14 where \mathbf{I} is the $p_i \times p_i$ identity matrix. Then the covariance matrix of the random
15 vector \mathbf{d}_i can be expressed as a second-order regression equation (Wang and Leblanc,
16 2008):

$$17 \quad \mathbf{d}_i \mathbf{d}_i^T = E \left[\left(\mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) + \mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)) \right) \left(\mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) + \mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)) \right)^T \right] + \mathbf{\Xi}, \quad (\text{A4})$$

18 where $\mathbf{\Xi}$ is a zero-mean error matrix. The expectation in (A4) has the decomposition

$$19 \quad E \left[\left(\mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) + \mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)) \right) \left(\mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) + \mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)) \right)^T \right] \\ 20 \quad = E \left[\mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t))^T \mathbf{R}_i^{-1/2} \right] + E \left[\mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)) (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f))^T \mathbf{R}_i^{-1/2} \right] \\ 21 \quad + E \left[\mathbf{R}_i^{-1/2} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)) (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f))^T \mathbf{R}_i^{-1/2} \right] + E \left[\mathbf{R}_i^{-1/2} (H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)) (\mathbf{y}_i^o - H_i(\mathbf{x}_i^t))^T \mathbf{R}_i^{-1/2} \right]. \quad (\text{A5})$$

22 Assuming the forecast and observation errors are statistically independent, we
23 have

$$1 \quad E\left[\mathbf{R}_i^{-1/2}\left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)\right)\left(H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)\right)^\top \mathbf{R}_i^{-1/2}\right] = \mathbf{R}_i^{-1/2} E\left[\left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)\right)\left(H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)\right)^\top\right] \mathbf{R}_i^{-1/2} = \mathbf{0}, \quad (\text{A6})$$

$$2 \quad E\left[\mathbf{R}_i^{-1/2}\left(H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)\right)\left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)\right)^\top \mathbf{R}_i^{-1/2}\right] = \mathbf{R}_i^{-1/2} E\left[\left(H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)\right)\left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)\right)^\top\right] \mathbf{R}_i^{-1/2} = \mathbf{0}. \quad (\text{A7})$$

3 From Eq. (2), $\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)$ is the observation error at the i -th time step, and hence,

$$4 \quad E\left[\mathbf{R}_i^{-1/2}\left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)\right)\left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)\right)^\top \mathbf{R}_i^{-1/2}\right]$$

$$5 \quad = \mathbf{R}_i^{-1/2} E\left[\left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)\right)\left(\mathbf{y}_i^o - H_i(\mathbf{x}_i^t)\right)^\top\right] \mathbf{R}_i^{-1/2}$$

$$6 \quad = \mathbf{R}_i^{-1/2} \mathbf{R}_i \mathbf{R}_i^{-1/2}$$

$$7 \quad = \mathbf{I}. \quad (\text{A8})$$

8 In a perfect system, truth would be statistically indistinguishable from one of the
9 ensemble forecast states, but in a real system this is not guaranteed. Hence, we use an
10 inflation factor to adjust the ensemble forecast states $\mathbf{x}_{i,j}^f$ to $\mathbf{x}_i^f + \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)$,
11 ($j=1, \dots, m$). Because the ensemble forecast states may be regarded as sample points of
12 \mathbf{x}_i^t (Anderson, 2007), we have

$$13 \quad E\left[\mathbf{R}_i^{-1/2}\left(H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)\right)\left(H_i(\mathbf{x}_i^t) - H_i(\mathbf{x}_i^f)\right)^\top \mathbf{R}_i^{-1/2}\right]$$

$$14 \quad = \frac{1}{m-1} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left(H_i(\mathbf{x}_i^f + \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)) - H_i(\mathbf{x}_i^f) \right) \left(H_i(\mathbf{x}_i^f + \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)) - H_i(\mathbf{x}_i^f) \right)^\top \mathbf{R}_i^{-1/2} \right]$$

$$15 \quad \equiv \mathbf{C}_i(\lambda). \quad (\text{A9})$$

16 Substituting Eqs (A5)-(A9) into Eq (A4), we have

$$17 \quad \mathbf{d}_i \mathbf{d}_i^\top = \mathbf{C}_i(\lambda) + \mathbf{I} + \mathbf{\Xi}. \quad (\text{A10})$$

18 It follows that the second-order moment statistic of error $\mathbf{\Xi}$ can be expressed as

$$19 \quad \text{Tr}\left[\mathbf{\Xi} \mathbf{\Xi}^\top\right] = \text{Tr}\left[\left(\mathbf{d}_i \mathbf{d}_i^\top - \mathbf{C}_i(\lambda) - \mathbf{I}\right)\left(\mathbf{d}_i \mathbf{d}_i^\top - \mathbf{C}_i(\lambda) - \mathbf{I}\right)^\top\right]$$

$$20 \quad \equiv L_i(\lambda). \quad (\text{A11})$$

21

22 **Appendix B: Derivation of $\dot{J}_{i/w}$ and $\ddot{J}_{i/w}$**

1 The first-order derivative of the objective function $J_i(\mathbf{w})$ (Eq. (10)) is

$$2 \quad \dot{J}_i(\mathbf{w}) = (m-1)\mathbf{w} - \sqrt{\hat{\lambda}_i} (\mathbf{X}_i^f)^T \dot{\mathbf{H}}_{i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}}^T \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}) \right], \quad (\text{B1})$$

3 where

$$4 \quad \dot{\mathbf{H}}_{i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}} = \left(\begin{array}{ccc} \frac{\partial h_{1,i}}{\partial \mathbf{x}_{1,i}} & \dots & \frac{\partial h_{1,i}}{\partial \mathbf{x}_{n,i}} \\ \vdots & \ddots & \vdots \\ \frac{\partial h_{p_i,i}}{\partial \mathbf{x}_{1,i}} & \dots & \frac{\partial h_{p_i,i}}{\partial \mathbf{x}_{n,i}} \end{array} \right)_{\mathbf{x}_i = \mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}} \quad (\text{B2})$$

5 is the first-order derivative of H_i evaluated at $\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}$. Then, the second-order
6 derivative of $J_i(\mathbf{w})$ is

$$7 \quad \ddot{J}_i(\mathbf{w}) = (m-1)\mathbf{I} + \hat{\lambda}_i (\mathbf{X}_i^f)^T \dot{\mathbf{H}}_{i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}}^T \mathbf{R}_i^{-1} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}} \mathbf{X}_i^f - \hat{\lambda}_i \mathbf{A}, \quad (\text{B3})$$

8 where \mathbf{A} is an $m \times m$ matrix with the (k, l) entry

$$9 \quad \left((\mathbf{x}_{i,k}^f - \mathbf{x}_i^f)^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f + \mathbf{X}_i^f \mathbf{w}} \otimes (\mathbf{x}_{i,l}^f - \mathbf{x}_i^f) \right)^T \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}) \right]. \quad (\text{B4})$$

10 The notation “ \otimes ” denotes an outer product operator of the block matrix defined in Eq.

11 (23). $\ddot{\mathbf{H}}_{i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}}$ is the second-order derivative of H_i at $\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}$, that is,

$$12 \quad \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}} \equiv \left(\begin{array}{c} \ddot{\mathbf{H}}_{1,i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}} \\ \vdots \\ \ddot{\mathbf{H}}_{p_i,i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}} \end{array} \right), \quad \ddot{\mathbf{H}}_{k,i|\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}} \equiv \left(\begin{array}{ccc} \frac{\partial^2 h_{k,i}}{\partial \mathbf{x}_{1,i} \partial \mathbf{x}_{1,i}} & \dots & \frac{\partial^2 h_{k,i}}{\partial \mathbf{x}_{1,i} \partial \mathbf{x}_{n,i}} \\ \vdots & \ddots & \vdots \\ \frac{\partial^2 h_{k,i}}{\partial \mathbf{x}_{n,i} \partial \mathbf{x}_{1,i}} & \dots & \frac{\partial^2 h_{k,i}}{\partial \mathbf{x}_{n,i} \partial \mathbf{x}_{n,i}} \end{array} \right)_{\mathbf{x}_i = \mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}}, \quad k=1, \dots, p_i. \quad (\text{B5})$$

13

14 **Appendix C: Details of the first-order approximation method in Sect. 2.2.1**

15 Suppose H_i can be approximated by its first-order Taylor expansion at \mathbf{x}_i^f ,

$$16 \quad H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}} (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)) \approx H_i(\mathbf{x}_i^f) + \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \sqrt{\hat{\lambda}} (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f). \quad (\text{C1})$$

17 The term $\mathbf{C}_i(\lambda)$ in Eq. (6) can be simplified to

$$\begin{aligned}
1 \quad C_i(\lambda) &\equiv \frac{1}{m-1} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left(H_i(\mathbf{x}_i^f + \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)) - H_i(\mathbf{x}_i^f) \right) \left(H_i(\mathbf{x}_i^f + \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)) - H_i(\mathbf{x}_i^f) \right)^T \mathbf{R}_i^{-1/2} \right] \\
2 \quad &= \frac{1}{m-1} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left(\dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) \right) \left(\dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \sqrt{\lambda}(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) \right)^T \mathbf{R}_i^{-1/2} \right] \\
3 \quad &= \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \frac{1}{m-1} \sum_{j=1}^m \left[(\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)^T \right] \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} \\
4 \quad &= \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2}.
\end{aligned}$$

5 It follows that the objective function $L_i(\lambda)$ of Eq. (5) can be simplified to

$$6 \quad L_{1,i}(\lambda) = \text{Tr} \left[\left(\mathbf{d}_i \mathbf{d}_i^T - \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} - \mathbf{I} \right) \left(\mathbf{d}_i \mathbf{d}_i^T - \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} - \mathbf{I} \right)^T \right]. \quad (\text{C2})$$

7 Because $L_{1,i}(\lambda)$ is a quadratic function of λ with positive quadratic coefficients, the
8 inflation factor can be easily expressed as

$$9 \quad \hat{\lambda}_i = \frac{\text{Tr} \left[\mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} (\mathbf{d}_i \mathbf{d}_i^T - \mathbf{I})^T \right]}{\text{Tr} \left[\mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} \right]}. \quad (\text{C3})$$

10 Similarly,

$$11 \quad H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}) \approx H_i(\mathbf{x}_i^f) + \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w}. \quad (\text{C4})$$

12 Substituting (C3) into Eq (8), we can simplify the objective function $J_i(\mathbf{w})$ to

$$13 \quad J_{1,i}(\mathbf{w}) = \frac{1}{2} (m-1) \mathbf{w}^T \mathbf{w} + \frac{1}{2} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} \right]^T \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} \right]. \quad (\text{C5})$$

14 The first-order derivative of $J_{1,i}(\mathbf{w})$ is

$$\begin{aligned}
15 \quad \dot{J}_{1,i}(\mathbf{w}) &= (m-1) \mathbf{w} - \left(\sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \right)^T \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} \right] \\
16 \quad &= (m-1) \mathbf{w} - \sqrt{\hat{\lambda}_i} (\mathbf{X}_i^f)^T \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} \right]. \quad (\text{C6})
\end{aligned}$$

17 Setting Eq (C6) to zero and solving it leads to

$$18 \quad \mathbf{w}_i^a = \left((m-1) \mathbf{I} + \hat{\lambda}_i \mathbf{X}_i^{fT} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \right)^{-1} \sqrt{\hat{\lambda}_i} \mathbf{X}_i^{fT} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1} (\mathbf{y}_i^o - H_i(\mathbf{x}_i^f)). \quad (\text{C7})$$

19 Lastly, the second-order derivative of $J_{1,i}(\mathbf{w})$ is

$$\ddot{\mathbf{J}}_{1,i}(\mathbf{w}) = (m-1)\mathbf{I} + \hat{\lambda}_i \mathbf{X}_i^{\text{f}\top} \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}}^{\text{T}} \mathbf{R}_i^{-1} \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \mathbf{X}_i^{\text{f}}. \quad (\text{C8})$$

2

3 Appendix D: Details of the second-order approximation method in Sect. 2.2.2

4 Suppose H_i can be approximated by its second-order Taylor expansion at \mathbf{x}_i^{f} ,

$$H_i(\mathbf{x}_i^{\text{f}} + \sqrt{\lambda}(\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})) \approx H_i(\mathbf{x}_i^{\text{f}}) + \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \sqrt{\lambda}(\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) + \frac{1}{2} \lambda \left((\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \otimes (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \right), (\text{D1})$$

6 The notation “ \otimes ” is defined as in Eq. (23). The term $\mathbf{C}_i(\lambda)$ in Eq. (7) can be

7 simplified to

$$\begin{aligned} \mathbf{C}_i(\lambda) &\equiv \frac{1}{m-1} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left(H_i(\mathbf{x}_i^{\text{f}} + \sqrt{\lambda}(\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})) - H_i(\mathbf{x}_i^{\text{f}}) \right) \left(H_i(\mathbf{x}_i^{\text{f}} + \sqrt{\lambda}(\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})) - H_i(\mathbf{x}_i^{\text{f}}) \right)^{\text{T}} \mathbf{R}_i^{-1/2} \right] \\ &= \frac{1}{m-1} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left(\dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \sqrt{\lambda}(\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) + \frac{1}{2} \lambda \left((\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \otimes (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \right) \right) \right. \\ &\quad \left. \cdot \left(\dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \sqrt{\lambda}(\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) + \frac{1}{2} \lambda \left((\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \otimes (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \right) \right)^{\text{T}} \mathbf{R}_i^{-1/2} \right] \\ &= \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \frac{1}{m-1} \sum_{j=1}^m \left[(\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})(\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \right] \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}}^{\text{T}} \mathbf{R}_i^{-1/2} \\ &\quad + \frac{\lambda^{3/2}}{2(m-1)} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \left((\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \otimes (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \right)^{\text{T}} \mathbf{R}_i^{-1/2} \right] \\ &\quad + \frac{\lambda^{3/2}}{2(m-1)} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left((\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \otimes (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \right) (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}}^{\text{T}} \mathbf{R}_i^{-1/2} \right] \\ &\quad + \frac{\lambda^2}{4(m-1)} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left((\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \otimes (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \right) \left((\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \otimes (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \right)^{\text{T}} \mathbf{R}_i^{-1/2} \right] \\ &= \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}}^{\text{T}} \mathbf{R}_i^{-1/2} - \lambda^{3/2} \mathbf{C}_{1,i} - \lambda^{3/2} \mathbf{C}_{1,i}^{\text{T}} - \lambda^2 \mathbf{C}_{2,i}. \quad (\text{D2}) \end{aligned}$$

16 where

$$\mathbf{C}_{i,1} = \frac{1}{2(m-1)} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \left((\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}})^{\text{T}} \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^{\text{f}}} \otimes (\mathbf{x}_{i,j}^{\text{f}} - \mathbf{x}_i^{\text{f}}) \right)^{\text{T}} \mathbf{R}_i^{-1/2} \right], \quad (\text{D3})$$

18 and

$$1 \quad \mathbf{C}_{i,2} = \frac{1}{4(m-1)} \sum_{j=1}^m \left[\mathbf{R}_i^{-1/2} \left((\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)^T \otimes \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) \right) \left((\mathbf{x}_{i,j}^f - \mathbf{x}_i^f)^T \otimes \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{x}_{i,j}^f - \mathbf{x}_i^f) \right)^T \mathbf{R}_i^{-1/2} \right] \quad (\text{D4})$$

2 are $p_i \times p_i$ matrices, which are independent of λ .

3 It follows that the objective function $L_i(\lambda)$ of Eq. (5) can be expressed as

$$4 \quad L_{2,i}(\lambda) = \text{Tr} \left[\left(\mathbf{d}_i \mathbf{d}_i^T - \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} - \lambda^{3/2} \mathbf{C}_{1,i} - \lambda^{3/2} \mathbf{C}_{1,i}^T - \lambda^2 \mathbf{C}_{2,i} - \mathbf{I} \right) \right. \\ 5 \quad \left. \cdot \left(\mathbf{d}_i \mathbf{d}_i^T - \lambda \mathbf{R}_i^{-1/2} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \hat{\mathbf{P}}_i \dot{\mathbf{H}}_{i|\mathbf{x}_i^f}^T \mathbf{R}_i^{-1/2} - \lambda^{3/2} \mathbf{C}_{1,i} - \lambda^{3/2} \mathbf{C}_{1,i}^T - \lambda^2 \mathbf{C}_{2,i} - \mathbf{I} \right)^T \right], \quad (\text{D5})$$

6 which is a polynomial algebraic equation $\lambda^{1/2}$.

7 Similarly,

$$8 \quad H_i(\mathbf{x}_i^f + \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w}) \approx H_i(\mathbf{x}_i^f) + \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w} + \frac{1}{2} \left(\left(\sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w} \right)^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes \left(\sqrt{\hat{\lambda}_i} \mathbf{X}_i^f \mathbf{w} \right) \right). \quad (\text{D6})$$

9 Substituting (D6) into Eq (10), we can simplify the objective function $J_i(\mathbf{w})$ to

$$10 \quad J_{2,i}(\mathbf{w}) = \frac{1}{2} (m-1) \mathbf{w}^T \mathbf{w} + \frac{1}{2} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} - \frac{\hat{\lambda}_i}{2} \left((\mathbf{X}_i^f \mathbf{w})^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{X}_i^f \mathbf{w}) \right) \right]^T \\ 11 \quad \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} - \frac{\hat{\lambda}_i}{2} \left((\mathbf{X}_i^f \mathbf{w})^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{X}_i^f \mathbf{w}) \right) \right]. \quad (\text{D7})$$

12 The first-order derivative of $J_{2,i}(\mathbf{w})$ is

$$13 \quad \dot{J}_{2,i}(\mathbf{w}) = (m-1) \mathbf{w} - \left[\sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f + \hat{\lambda}_i \mathbf{B}_1 \right]^T \\ 14 \quad \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} - \frac{\hat{\lambda}_i}{2} \left((\mathbf{X}_i^f \mathbf{w})^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{X}_i^f \mathbf{w}) \right) \right], \quad (\text{D8})$$

15 where \mathbf{B}_1 is a $p_i \times m$ matrix with the (k, l) entry $\mathbf{X}_{i,l}^{f,T} \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f, k} \mathbf{X}_i^f \mathbf{w}$.

16 The second-order derivative of $J_{2,i}(\mathbf{w})$ is

$$17 \quad \ddot{J}_{2,i}(\mathbf{w}) = (m-1) \mathbf{I} + \left[\sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f + \hat{\lambda}_i \mathbf{B}_1 \right]^T \mathbf{R}_i^{-1} \left[\sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f + \hat{\lambda}_i \mathbf{B}_1 \right] - \hat{\lambda}_i \mathbf{B}_2. \quad (\text{D9})$$

18 where \mathbf{B}_2 is an $m \times m$ matrix with the (k, l) entry

$$\left((\mathbf{x}_{i,k}^f - \mathbf{x}_i^f)^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{x}_{i,l}^f - \mathbf{x}_i^f) \right)^T \mathbf{R}_i^{-1} \left[\mathbf{y}_i^o - H_i(\mathbf{x}_i^f) - \sqrt{\hat{\lambda}_i} \dot{\mathbf{H}}_{i|\mathbf{x}_i^f} \mathbf{X}_i^f \mathbf{w} - \frac{\hat{\lambda}_i}{2} \left((\mathbf{X}_i^f \mathbf{w})^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{X}_i^f \mathbf{w}) \right) \right].$$

2

3 **Appendix E: Computational feasibility**

4 We take the radiative transfer model (RTTOV) as an example of observation
 5 operators in numerical weather prediction to discuss the computational feasibility of the
 6 ETKF with second-order approximation assimilation method. Generally speaking, the
 7 ensemble size m is from tens to hundreds, the dimension of observations (including
 8 gauge observations and AMSU brightness temperature) p_i is hundreds of thousands,
 9 and the dimension of state vector n is tens of millions. If the storage and the number of
 10 multiplications for computing any array are not in the dimension of $n \times n$, $n \times p_i$ or
 11 $p_i \times p_i$, the computation should be feasible.

12 In our proposed ETKF with second-order approximation, the most expensive part
 13 is in computing the array

$$(\mathbf{X}_i^f \mathbf{w})^T \otimes \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f} \otimes (\mathbf{X}_i^f \mathbf{w}) = \left\{ (\mathbf{X}_i^f \mathbf{w})^T \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f,1} \mathbf{X}_i^f \mathbf{w}, \dots, (\mathbf{X}_i^f \mathbf{w})^T \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f,p_i} \mathbf{X}_i^f \mathbf{w} \right\}. \quad (\text{E1})$$

15 Therefore, we only discuss the problems related to the computation of

$$(\mathbf{X}_i^f \mathbf{w})^T \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f,k} \mathbf{X}_i^f \mathbf{w}.$$

17

18 *a. Storage problems*

19 By the matrix multiplication rule,

$$(\mathbf{X}_i^f \mathbf{w})^T \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f,k} \mathbf{X}_i^f \mathbf{w} = \mathbf{w}^T \left((\mathbf{X}_i^f)^T \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f,k} \mathbf{X}_i^f \right) \mathbf{w}, \quad (\text{E2})$$

21 where the matrix in the middle of the right hand-side of Eq. (E2)

$$1 \quad (\mathbf{X}_i^f)^T \ddot{\mathbf{H}}_{i|\mathbf{x}_i^f, k} \mathbf{X}_i^f \quad (E3)$$

2 is of dimension $m \times m$, because subscript k runs from 1 to p_i , the size of the array in
 3 Eq. (E1) is $m \times m \times p_i$. Therefore, there is no storage problem to save this array.

4

5 *b. The computational cost of Eq. (E3)*

6 Usually, $mn(m+n)$ times multiplication are required to compute a matrix such
 7 as the one in Eq. (E3). However, in the case of the RTTOV observation operator,
 8 $\ddot{\mathbf{H}}_{i|\mathbf{x}_i^f, k}$ is a sparse matrix with a large number of zeros and the non-zero part has a
 9 simple regular structure. This is because an MSU brightness temperature measurement
 10 on a grid point (denoted by $y_i^o(k)$) is only related to the meteorological state variables
 11 on the transmission route. Suppose the meteorological model has 50 layers and 6 types
 12 of variables, the number of state variables on the transmission route of the MSU
 13 brightness temperature $y_i^o(k)$ is approximately $s=300$. For the variables not on the
 14 transmission route, the corresponding entries in $\ddot{\mathbf{H}}_{i|\mathbf{x}_i^f}(k)$ (Eq. (22)) are zero. Therefore,
 15 the computation of Eq. (E3) only requires $ms(m+s)/2$ times of multiplication.

16 On the other hand, computing the first and second derivatives requires additional
 17 number of operations, but it is manageable.
