

1 Dear Prof. Vicente Perez-Munuzuri  
2 Editor  
3 Nonlinear Processes in Geophysics  
4

5 You will find ci-joint the new version of our manuscript “Nonlinear analysis of the  
6 occurrence of hurricanes in the Gulf of Mexico and the Caribbean Sea”. We provide a  
7 point-by-point list of each comments by the reviewers. English was significant  
8 improved by the Elsevier Language Editing Services, so we cannot indicate where in  
9 the manuscript the English revision appears. What we do is indicate the changes of the  
10 point-by-point list of each comments by the reviewers (page #, line #).

1. *For example, it is not clear for me that the time series is stationary. May you calculate the probability density function for the half and full data length and compare the results. Of course after the detrend has been done.*

**Reply:** Two tests were done to see the stationarity of the series, one of which was the Dickey-Fuller test (D-F), which is the standard test to prove the stationarity of a series. They consider three different regression equations that can be used to prove the presence of a unit root, the parameter of interest of these equations is  $\mathbf{r}$ , if  $\mathbf{r} = \mathbf{1}$  the series has a unit root. In this test the null hypothesis where  $H_0: \mathbf{r} = \mathbf{1}$  shows that the series has unit root and is not stationary, and if  $H_a: \mathbf{r} < 1$  then the series is stationary. Using this test, a value of D-F = -5.7753 was obtained with a p-value = 0.01, which is statistically significant and therefore we can say that our series is stationary.

Now, following the test suggested by the reviewer. Since a series is stationary over time when its mean and variance are constant over time, the respective values were obtained for the middle of the series and for the complete series. The values of the mean and variance of the complete series were: mean = 0.138 and variance = 0.020. The values for the middle of the series were: mean = 0.123 and variance = 0.0199, so this requirement is also met. Finally, the probability density function was plotted for 1749-1881 and 1749-2012, as well as their respective histograms, with this we can see how the form of the function and the histogram are conserved over time.

38

43

Figure 1. (Left) Histogram from the Hurricane series 1749-2012. (Right) Histogram for the Hurricane series 1749-1881. It is possible to observe how the distribution of the histogram is preserved for the middle of the series and for the complete series.

44  
45  
46 Figure 2. (Left) Probability density function of the Hurricane series 1749-2012.  
47 (Right) Probability density function for the Hurricane series of 1749-1881. It is  
48 possible to observe how the distribution of the function is preserved for the middle  
49 of the series and for the complete series.

- 50  
51  
52 2. *Concerning the Poincaré map I continue to have some doubts as may not be*  
53 *useful. I can think of a 5-dimensional quasiperiodic signal that shows an*  
54 *irregular two-dimensional Poincaré map, and however the original time series is*  
55 *not chaotic I recommend deleting that figure and the corresponding comments.*

56  
57 **Reply:** The section corresponding to this part has already been deleted.

- 58  
59 3. *The new results of the Lyapunov coefficient as a function of the embedding*  
60 *dimension and the time delay which are shown in the answer do not appear in the*  
61 *manuscript. I think they should.*

62  
63 **Reply:** The new results were already put in the text. See page 14, lines 313-315

- 64  
65 4. *One of the main objectives of using these nonlinear methods not only lie in*  
66 *obtaining an embedding dimension and showing the chaotic nature of the time*  
67 *series, but to perform some forecasting. What will happen if you try to reconstruct*  
68 *the time series for example, using only half of its length. This was mentioned in*  
69 *my previous review.*

70  
71 **Reply:** = By means of non-linear methods, the entropy test was performed, which  
72 showed a predictability value of 2.78 years, and means of the locally linear  
73 prediction (making the prediction at one step), the same value was obtained. The  
74 procedure for this method is as follows: The last known state of the system,  
75 represented by a vector  $x = [x(n), x(n + \tau), \dots, x(n + (m-1) \tau)]$ , is determined, where  
76  $m$  is the embedment dimension and  $\tau$  is the delay time. Then we have found  $p$   
77 nearby states (usually close neighbors of  $x$ ) of the system that has happened in the  
78 past, from calculating their distances of  $x$ . The idea is then to adjust a map that  
79 extrapolates  $x$  and its neighboring  $p$  to determine the following values” (Dasan et al.,  
80 2002). Based on the above, the value of the embedding dimension and the delay

81 time were changed, in order to see in which values better results were obtained; this  
82 was possible with a dimension of  $m = 4$  and  $\tau = 9$ , which are the values with which  
83 the attractor of the system was obtained. Therefore, a good prediction is possible  
84 until  $t = t_0 + 3$ . It is not possible to reproduce half of the series since the system tells  
85 us that we can only do it for two years.

86  
87 Dasan, J., Ramamohan, R. T., Singh, A., y Prabhu, R. N. (2002) Stress fluctuations

91

## Answers to the Third Reviewer

93 1. *The manuscript presents nonlinear analysis of the occurrence of hurricanes in the*  
 94 *Gulf of Mexico and the Caribbean Sea, which is interesting. The subject addressed is*  
 95 *within the scope of the journal.*

96

97 2. *However, the manuscript, in its present form, contains several weaknesses.*  
 98 *Appropriate revisions to the following points should be undertaken in order to justify*  
 99 *recommendation for publication.*

100

101 3. *Full names should be shown for all abbreviations in their first occurrence in texts.*  
 102 *For example, 2-D in p.6, etc.*

103

104 **Reply:** done

105

106 4. *For readers to quickly catch your contribution, it would be better to highlight major*  
 107 *difficulties and challenges, and your original achievements to overcome them, in a*  
 108 *clearer way in abstract and introduction.*

109

110 **Reply:** Already added to the text. See page 1 y 2, lines 21-22, 40-44

111

112 5. *It is shown in the reference list that the authors have a pertinent publication in this*  
 113 *field. This raises some concerns regarding the potential overlap with their previous*  
 114 *works. The authors should explicitly state the novel contribution of this work, the*  
 115 *similarities and the differences of this work with their previous publications.*

116

117 **Reply:** Indeed, we have a publication about the hurricanes that occurred in the same  
 118 study area for the same time interval (1749-2012). However, in this case, our analysis  
 119 focused on a different approach, for this article we apply different methods of spectral  
 120 analysis (Wavelets, Fast Fourier Transform, Multi-taper and Maximum Entropy), in  
 121 order to see if there was a relationship between the occurrence of hurricanes and the  
 122 periodicity of sunspots.

123

124 An exhaustive analysis was carried out on the type of correlation between the two  
 125 systems, as well as the lag between both events. Finding a considerable relationship  
 126 between the two systems, not only with the periodicities, but also with the type of  
 127 correlation.

128

129 The substantial difference between the previous article and this one, is that this time we  
 130 are focusing on the behavior of only the hurricanes, performing a non-linear analysis,  
 131 the main objective was to find out if the hurricanes belong to the chaotic dynamic  
 132 systems. When comparing both studies (spectral analysis and non-linear analysis) we  
 133 realized that hurricanes have the so-called "chaotic edge". This is the most important  
 134 contribution of our work, since it tells us that hurricanes can behave periodically and

135 follow a pattern, but this does not hold all the time, their behavior goes to a threshold at  
136 which it is chaotic.

137

138 **6. *It is mentioned in p.1 that historical records of 1749 to 2012 are taken. Why are***  
139 ***more recent data not included in the study?***

140

141 **Reply:** This was a study that was carried out during the year of 2012, until then, recent  
142 information was taken.

143

144 **6.1. *Is there any difficulty in obtaining more recent data?***

145

146 **Reply:** Of course not, the HURDAT page updates its data every year after the end of  
147 hurricane season in the Atlantic Ocean, Caribbean Sea and Gulf of Mexico. Well it's  
148 the official hurricanes record of USA for this area.

149

150 **6.2. *Are there any changes to situation in recent years? What are its effects on the***  
151 ***result?***

152

153 **Reply:** We must not forget that this type of studies provides us with information about  
154 the dynamics of an underlying system, so that, once we have found that our system is  
155 chaotic, it will not let being chaotic even if we obtain the record of the missing years  
156 (i.e., 2013-2017). Therefore, the absence of this data does not affect our result.

157

158 **7. *It is mentioned in p.1 that the Gulf of Mexico and the Caribbean Sea are adopted as***  
159 ***the case study. What are other feasible alternatives?***

160

161 **Reply:** We can study the hurricanes of the Pacific Ocean, which is another area  
162 impacted by the occurrence of hurricanes, for this part we can analyze those occurred  
163 in the Mexican territory, and those observed in China, Japan and the Philippines. In the  
164 same way, they are observed in Australia and India.

165

166 **7.1. *What are the advantages of adopting this particular case study over others in this***  
167 ***case?***

168

169 **Reply:** The importance of this project and the reason why this region was studied, is  
170 because there was a fairly substantial record of the hurricanes that occurred in the Gulf  
171 of Mexico and the Caribbean Sea since 1749. The other regions impacted by hurricanes  
172 do not have such a long historical record. Having a record of this magnitude was  
173 important for the spectral analysis that was developed, on the other hand the length of  
174 the time series, also allowed the development of non-linear analysis, since with less  
175 available data it would then be impossible to think to do this type of analysis.

176

177 **7.2. *How will this affect the results? The authors should provide more details on this.***

178

179 **Reply:** As mentioned above, the study area was chosen taking into account the long  
180 historical record that was available. Even at present, the data in the other regions  
181 impacted by hurricanes, would not be enough to perform a non-linear analysis, at least  
182 for the case in which we want to study the occurrence of these phenomenon.  
183

184 8. *It is mentioned in p.1 that HURDAT is adopted as the database. What are other*  
185 *feasible alternatives?*  
186

187 **Reply:** There is the National Hurricane Center (NHC) -NOAA (National Oceanic and  
188 Atmospheric Administration), which is a regional specialized meteorological center for  
189 the North Atlantic and the Eastern Pacific, created with the purpose of creating a  
190 hurricane warning network. HURDAT considered the annual registration of this center.  
191

192 8.1. *What are the advantages of adopting this particular database over others in this*  
193 *case? How will this affect the results? The authors should provide more details on*  
194 *this.*  
195

196 **Reply:** Both HURDAT and NHC-NOAA are official records of the United States and  
197 HURDAT bases its database on the NHC report, apart from its own re-analysis project,  
198 therefore, we consider that our results could not be affected. We have not only reliable  
199 historical data, but also data obtained from the official records of the United States.  
200

201 9. *It is mentioned in p.1 that spectral analysis is adopted for the nonlinear analysis of*  
202 *the hurricanes time series. What are other feasible alternatives?*

203 **Reply:** In fact, the first hint of chaotic behavior can be seen from a spectral analysis.  
204 "Spectral power analysis is often used to distinguish chaotic or quasi-periodic behavior  
205 from periodic structures and to identify different periods embedded in a chaotic signal"  
206 (Zeng et al., 1990). According to Schuster (1988) and Tsonis (1992) the power  
207 spectrum is not only characteristic of a process of deterministic chaos, but also of a  
208 linear stochastic process. That is why more studies should be done and for this reason.  
209 Other than this first approach, we have the Hurst exponent and the phase space graph,  
210 these results are presented in our result section.

211 9.1. *What are the advantages of adopting this particular approach over others in this*  
212 *case? How will this affect the results? The authors should provide more details on*  
213 *this.*  
214  
215

216 **Reply:** As we mentioned before, spectral analysis is a tool that is used to see possible  
217 indications of a chaotic behavior, however, it cannot always be appreciated and that is  
218 why the corresponding methods of non-linear analysis are used.  
219

220 **10. It is mentioned in p.5 that three methods are adopted to know the properties of the**  
221 **system. What are other feasible alternatives?**  
222

223 **Reply:** There are the bifurcation diagrams which are abrupt changes of the geometry of  
224 the attractor or of the topology in a critical value of the control parameter. In this type  
225 of diagrams, it is possible to see periodic and chaotic regimes, there are five different  
226 types of bifurcation diagrams, which provide a route to chaos. In fact, these types of  
227 diagrams can be compared with the graph of the Lyapunov exponent. For example, for  
228 a logistic map, it can be seen how the Lyapunov exponent goes from negative values in  
229 the regular regions of the bifurcation diagram, to positive values in the chaotic regions,  
230 becoming zero at the bifurcation points. In the chaotic region we can see regular  
231 behavior windows, in which the exponent becomes negative again. On the other hand,  
232 we have the Horizontal Visibility graph method, which “offers a promising new  
233 method for the development of time series analysis, mainly because it has been  
234 corroborated that the fundamental nature of quite different complex dynamic processes  
235 is inherited for the associated visibility charts” (Núñez et al., 2013). The Horizontal  
236 Visibility graphic allow us to describe chaotic, fractal-stochastic and dissipative  
237 processes.  
238

239 **10.1. What are the advantages of adopting these particular methods over others**  
240 **in this case? How will this affect the results? The authors should provide more**  
241 **details on this.**  
242

243 **Reply:** The methods used are as good as those mentioned above. If the Visibility graph  
244 had been used, the advantage would have been not having to calculate the rest of the  
245 parameters such as: delay time, Theiler window, embedding dimension, etc.; however,  
246 we do not use this method because it requires thousands of data.  
247

248 **11. It is mentioned in p.6 that the algorithms proposed by Kantz (1994) and Rosenstein**  
249 **et al. (1993) are adopted to compute the Lyapunov exponent. What are other feasible**  
250 **alternatives? What are the advantages of adopting these particular algorithms over**  
251 **others in this case? How will this affect the results? The authors should provide**  
252 **more details on this.**  
253

254 **Reply:** There is the algorithm of Wolf et al. (1985), in which the maximum exponent  
255 of Lyapunov can also be calculated from a data set, following the long-term evolution  
256 of one of the main axes. However, it is a highly sensitive method and can easily lead to  
257 an erroneous result. Rosenstein and Kantz, more than suggesting a trajectory, used the  
258 complete data set and essentially calculated a trajectory for each pair of nearby  
259 neighbors. The two algorithms are substantially similar and calculate the maximum  
260 exponent of Lyapunov by looking for all the neighbors within a neighborhood of the  
261 reference trajectory and calculating the average distance between the neighbors and  
262 that trajectory as a function of time or relative time scale for the data sampling rate.  
263 Having used the algorithm of Wolf et al. (1985) a positive Lyapunov exponent would  
264 have been obtained without guaranteeing that the system has a chaotic dynamic, since  
265 this algorithm always gives a positive exponent.  
266

267 12. *It is mentioned in p.6 that the Poincaré surface is adopted to detect some kind of*  
268 *chaotic behavior. What are other feasible alternatives? What are the advantages of*  
269 *adopting this particular approach over others in this case? How will this affect the*  
270 *results? The authors should provide more details on this.*

271  
272 **Reply:** The other alternatives are those presented at the present work; In fact, in our  
273 study we did not rely on the results obtained by a single method, but we used several  
274 methods, in order to corroborate each result.

275  
276 13. *It is mentioned in p.6 that the “delay method” is adopted to have a qualitative idea of*  
277 *the number of hurricanes that occurred. What are other feasible alternatives? What*  
278 *are the advantages of adopting this particular method over others in this case? How*  
279 *will this affect the results? The authors should provide more details on this.*

280  
281 **Reply:** The “delay method” was used to construct the phase space of the system, once  
282 the delay time and the embedment dimension were obtained. It was a method created  
283 precisely for the case where we have a discrete system, that is, a set of data; so far it is  
284 the only method.

285  
286 14. *It is mentioned in p.7 that three different methods are adopted to calculate the time*  
287 *lag. What are other feasible alternatives? What are the advantages of adopting these*  
288 *particular methods over others in this case? How will this affect the results? The*  
289 *authors should provide more details on this.*

290  
291 **Reply:** The delay time can also be obtained by constructing the phase space from an  
292 arbitrary time delay, later, by trial and error, testing with other values until the  
293 trajectories are more visible; however, this form does not give a very reliable value of  
294 the delay time. That is why we used the mentioned methods, which are, until now, the  
295 most reliable.

296  
297 15. *It is mentioned in p.10 that the Kaplan-Yorke Dimension is adopted to see the*  
298 *attractor dimension. What are other feasible alternatives? What are the advantages*  
299 *of adopting this particular method over others in this case? How will this affect the*  
300 *results? The authors should provide more details on this.*

301  
302 **Reply:** There is a whole family of fractal dimensions  $D_q$ , which are called Renyi  
303 dimensions, the way you can see them is through a partition of the phase space: For the  
304 number of boxes  $N_\epsilon$  of size  $\epsilon$ , you need to cover a fractal set with scales of dimension  
305  $D_0$ . In  $D_0$  we have another type of dimension, which is the so-called capacity  
306 dimension, which is closely related to the dimension of Hausdorff, which is from the  
307 mathematical point of view, the most natural concept to characterize fractal sets. On  
308 the other hand, there is also the Information dimension, which takes into account the  
309 relative frequency of visits of the trajectory, making this type of dimension more  
310 attractive for physical systems. However, the Integral and the Correlation Dimension  
311 were made to characterize measured data, as well as being more robust and efficient  
312 estimators. Successive elements of a time series are not usually independent, but the

313 last two mentioned methods involve phase space vectors such as the location of points  
314 in an attractor. This is why they are the most used and most reliable.

315

316 **16. It is mentioned in p.13 that the criterion of Ruelle (1990) is adopted to corroborate**  
317 **that the obtained dimension of the attractor is reliable. What are other feasible**  
318 **alternatives? What are the advantages of adopting this particular criterion over**  
319 **others in this case? How will this affect the results? The authors should provide**  
320 **more details on this.**

321

322 **Reply:** We also have the criterion suggested by Tsonis et al. (1993), assuming that  
323  $M \sim 10^{2+0.4v_2}$  data points are needed for a reliable estimate of the fractal dimension  $v_2$ .  
324 If this criterion is used, our data does not meet the requirement; however, they agree  
325 with the requirements of Ruelle (1990) and there is no stipulation that requires that the  
326 systems must have both requirements, so it is sufficient for the system to agree with  
327 one of them in order for the dimension to be reliable.

328

329 **17. It is mentioned in p.14 that the Iterated Functions System test is adopted to confirm**  
330 **that there is a stable attractor. What are other feasible alternatives? What are the**  
331 **advantages of adopting this particular test over others in this case? How will this**  
332 **affect the results? The authors should provide more details on this.**

333

334 **Reply:** The Iterated Functions system is used to make an adequate visualization of fine  
335 details that are present in the time series, including the self-similarity, therefore it can  
336 reveal the correlations in the data and help characterize its "color" (referring to the type  
337 of noise). As for the techniques that are used for the characteristic of the data, we also  
338 have the Hurst exponent, which also characterizes the color of the noise. Both methods  
339 are used in our study. The results obtained from both methods help to complement our  
340 discussion.

341

342 **18. It is mentioned in p.15 that "...test showed that the occurrence of hurricanes in the**  
343 **Gulf of Mexico and the Caribbean Sea is chaotic with high dimensionality. One**  
344 **possible explanation is..." More justification should be furnished on this issue.**

345

346 **Reply:** It has already been added to the text, see page 14 y 15, line 316-343.

347

348 **19. Some key parameters are not mentioned. The rationale on the choice of the**  
349 **particular set of parameters should be explained with more details. Have the authors**  
350 **experimented with other sets of values? What are the sensitivities of these**  
351 **parameters on the results?**

352

353 **Reply:** We do not understand to what key parameters it refers. The parameters that  
354 were used were: 1) The Theiler window, which was obtained from the space-time  
355 separation graph. The value of this window is very important because it prevents  
356 spurious dimensions from being obtained in the attractor. In fact, if a good Theiler  
357 window is not chosen, it is not possible to extract the embedding dimension. 2) On the  
358 other hand we have the delay time and the dimension of embebimiento, with these  
359 values the tests were also made, as it is explained in the article; the purpose of

360 changing these values was to corroborate the existence of the chaotic behavior in a  
361 quantitative way, through the change in the values of the exponent of Lyapunov with  
362 the decrease of the dimension of embebimento, and qualitatively, when observing the  
363 invariant behavior in the graphs of the exponent. 3) Change in the radius of the  
364 neighborhood in which the reference point was chosen; this radius should be as small  
365 as possible but large enough so that on average each reference point has at least some  
366 neighbors. 4) Reference points, initially 500 points are an appropriate choice but  
367 should be changed if the data are intermittent or the computation time is fast and 5)  
368 Neighbors close to these points.

369

370 **20. *Some assumptions are stated in various sections. Justifications should be provided***  
371 ***on these assumptions. Evaluation on how they will affect the results should be made.***

372

373 **Reply:** Added to the text, see page 3, 5, 6, 7-10, 14-15, line 88-94, 114-116, 149-164,  
374 178-184, 191-205, 214-216, 220-225, 238, 305-311, 320-334, 338-343

375

376 **21. *The discussion section in the present form is relatively weak and should be***  
377 ***strengthened with more details and justifications.***

378

379 **Reply:** Added to the text, see discussion section

380

381 **22. *Moreover, the manuscript could be substantially improved by relying and citing***  
382 ***more on recent literatures about contemporary real-life case studies of modelling***  
383 ***techniques in hydrologic engineering such as the followings:***

384

385 **Reply:** The authors are grateful for the comment, the following references were taken  
386 into account
