#### 11 Abstract

Climate change is expressed as a climate system transiting from the initial state to a 12 13 new state in a short time. The period between the initial state and the new state is defined as transition process, which is the key part to connect the two states. By using 14 a piece-wise function, the transition process is stated approximately (Mudelsee, 2000). 15 However, the dynamic processes are not included in the piece-wise function. Thus, we 16 had proposed a method (Yan et al, 2015, 2016) to study the transition process by using 17 a continuous function. In this manuscript, this method is developed to predict the 18 19 uncompleted transition process based on the dynamic characteristics of the continuous function. We introduce this prediction method in details and apply it to three ideal 20 time sequences and the Pacific Decadal Oscillation (PDO). The PDO is a long-lived 21 El Niño-like pattern of Pacific climate variability (Barnett et al, 1999). This method 22 reveals a new quantitative relationship during the transition process, which explores a 23 nonlinear relationship between the linear trend and the amplitude (difference) between 24 25 the initial state and the end state. As the transition process begins, the initial state and the linear trend are estimated. Then, according to the relationship, the end state and 26 end moment of the uncompleted transition process is predicted. 27

#### 1 Decadal Oscillation

#### 2 **1. Introduction**

A system transiting from one stable state to another in a short period is called 3 abrupt change (Charney and DeVore, 1979; Lorenz, 1963, 1979). The abrupt change 4 system has two or more states (Goldblatt et al, 2006; Alexander et al, 2012), the 5 system swings between these states that are also called attractors in physics. This 6 phenomena is verified in many fields including biology (Nozaki, 2001), ecology 7 8 (Osterkamp et al, 2001), climatology (Thom, 1972; Overpeck and Cole, 2006; Yang et 9 al, 2013a, 2013b), brain science (Sherman et al, 1981), etc. The latest observed climate change event is global warning hiatus, which has been studied deeply by 10 11 many researchers (Amaya et al, 2018; Kosaka and Xie, 2013; Yang et al, 2017). Seven different kinds of abrupt changes are mentioned in Thom's research(1972). Over the 12 13 last several decades, many methods have been proposed to identify different kinds of abrupt change (Li et al, 1996), such as Moving T-Test, Cramer's (Wei, 1999), 14 Mann-Kendall (MK, Goossens and Berger, 1986), Fisher (Cabezas and Fath, 2002), 15 16 etc. It is noticed that most abrupt change detection methods suggest that the abrupt 17 change is around a turning point. The significant difference between the average 18 values of the two sequences on both two sides of the turning point is defined as the index to measure the abrupt change. This kind of detection method has a drawback. It 19 is difficult to detect the abrupt change that occurs at the end of sequence. 20

21 Mudelsee (2000) studied the abrupt change of a time sequence and illustrated that abrupt change has a duration, which can be quantitatively described with a 22 23 piece-wise (ramp) function. We developed the detection method by using a continuous function to replace the ramp function (Yan et al, 2014, 2015). The new 24 method can confine the beginning and ending points of abrupt change and 25 quantitatively describes the process of abrupt climate change, and three parameters 26 27 are introduced. A quantitative relationship among the parameters is revealed (Yan et al, 2015). The relationship could be used to predict the end moment (state) if the system 28

had left the original state but not yet reached to the new state, which is defined as an
uncompleted transition process.

3 In this manuscript, three ideal time sequences are tested to study the prediction method. The prediction method is also applied to study the climate transition process 4 of the PDO, which is an important signal that reveals climatic variability on the 5 decadal timescale (Mantua et al, 1997; Barnett et al, 1999; Zhang et al, 1997; Yang et 6 al, 2004). Previous studies (Lu et al, 2013; Trenberth and Hurrell, 1994) have 7 8 indicated that there are many abrupt changes in the PDO over the past 100 years. 9 Most researches mentioned the climate changes happened in the 1940s and 1970s. During the 1940s, the PDO transited from a high state to a low state, while during the 10 1970s, it did the opposite. All of these changes and their processes had been studied in 11 12 our previous research (Yan et al, 2015 2016). The climate transition processes were explored clearly. However, we still can not know when the transition processes finish 13 their increasing or decreasing to a stable state if the transition process has begun. We 14 15 develop a new method to predict the end state and the end moment of a transition 16 process based on the quantitative relationship.

#### 17 **2. Methods**

It is necessary to describe the transition process quantitatively before the prediction of the uncompleted climate transition process. We had proposed a detection method by using the logistic model to obtain a transition process. In section 2.1, the method is introduced briefly. On the basis of the detection method, the prediction method for studying the uncompleted transition process is further developed in section 2.2.

24

#### 2.1 The detection method of transition process

The real time sequence changes abruptly as shown in figure 1a, and the system jumps to a high state in point C. If the period around point C is observed on a shorter time scale (as shown figure 1b), a transition period is obtained, and it is a part of the

original time sequence. In fact, many abrupt changes could be considered to be a transition period with a more detailed view. The transition period was expressed with a ramp function in Mudelsee's research (2000) as shown in figure 1c, and the time sequence is divided into three segments, including two equilibrium states and one increasing state. The ramp function is as follows:

$$6 \qquad x_t = \begin{cases} x_1 & t \le t_1 \\ x_1 + (t - t_1)(x_2 - x_1)/(t_2 - t_1) & t_1 \le t \le t_2 \\ x_2 & t \ge t_2 \end{cases}$$
(1)

where t represents time, and  $x_t$  represent the system states, which is obtained by the 7 linear regression method. It is noted that the climate system is continuous; it is even 8 9 the sampling sequence that makes it is discontinuous. We used a continuous function 10 to express this transition period approximately, and we also created a novel method to 11 detect the transition period (Yan et al, 2015). Here, the detection method is introduced 12 briefly. The continuous evolution of the logistic model is consistent with the transition process (May, 1976), which is shown in figure 1d. The modified logistic model is 13 14 expressed as follows:

15 
$$\dot{x} = k(x-u)(v-x)$$
 (2)

16 Parameters u and v represent the two equilibrium states respectively. Parameter krepresents the switching between different states, and it is defined as the instability 17 parameter. As shown in figure 2a, parameters u and v being fixed, and setting k as 0.5, 18 19 the system transiting to the new state costs a shorter time than that setting k as 0.4. If 20 parameter k is set large enough, the system collapses and becomes chaotic ( as shown in figure 2b). When parameter k is set to different values, more situations have been 21 22 discussed in detail in the previous research (Yan et al, 2016). The result shows that parameter k characterizes the stability of the system (the larger the absolute value, the 23 more unstable the system). According to Thom's theory (1972), the system described 24 by a quartic function would exhibit tipping-point abrupt change in which the system 25 jumps from one state to a new state abruptly. Thus, we did some mathematical 26 27 derivation to Eq. (2), and the general potential energy is obtained as follows:

$$V_{(x)} = -\int_{0}^{x} \ddot{x} dx = -\int_{0}^{x} 2k^{2} [x - (u + v)/2] (x - u) (x - v) dx$$

$$= \frac{k^{2}}{2} [x^{4} - 2(u + v)x^{3} + (u^{2} + v^{2} + 4uv)x^{2} - 2(u + v)uvx]$$
(3)

2 It means that Eq. (2) describes a system with tipping-point abrupt change. In figure 2c, the potential energy of Eq. (3) is verified to have two states with the lowest 3 energy, and both of them are stable. This bistable structure is common in the climate 4 5 system (Goldblatt et al, 2006). Therefore, Eq. (2) can be used to describe the abrupt 6 change system, and the parameters represent different key factors of the transition 7 period during abrupt change. Then, the parameters u, v and h are obtained by the regression method (Huang, 1990; Yang et al, 2013a) by using Eq. (4), where i,  $x_i$ 8 denote the time and the state of the system at this time, and  $\overline{i}, \overline{x}_i$  are their averages 9 10 respectively. Variable  $n_2$  is the length of the second segment.

11  

$$\begin{cases}
\nu = \sum_{i=1}^{n_{1}} x_{i} / n_{1} \\
u = \sum_{i=n_{1}+n_{2}+1}^{n} x_{i} / n_{3} \\
h = \sum_{i=n_{1}+1}^{n_{1}+n_{2}} \overline{i} \cdot \overline{x}_{i} / \sum_{i=n_{1}+1}^{n_{1}+n_{2}} \overline{i}^{2} \cdot 
\end{cases}$$
(4)

12 The linear trend *h* represents the ratio of system state change to time, and it can 13 be expressed by two points on the curve approximately as Eq. (5), where the two 14 points are  $A(x_a, t_a)$  and  $B(x_b, t_b)$ .

15 
$$h = \frac{x_a - x_b}{t_a - t_b}$$
 (5)

As shown in figure 2d, the transition period during point  $A(x_a, t_a)$  and point  $B(x_b, t_b)$  is approximately linear. Then, we can use the location parameters  $\alpha$ ,  $\beta$  to express system states  $x_a$  and  $x_b$ . By solving Eq. (2), the relationship between x and t is determined.

20 
$$t = \frac{1}{k(u-v)} \ln(\frac{x_0 - u}{x_0 - v} \cdot \frac{x - v}{x - u}) + t_0$$
(6)

.

Then, parameter h is rewritten as Eq. (7). It is noted that the rightmost part is
 only related to the location parameters α and β, then let it be χ. Then, the relationship
 of Eq. (7) is rewritten as Eq. (8):

$$h = \frac{x_b - x_a}{\frac{1}{(\mu - \nu)k} \ln \frac{x_0 - \mu}{x_0 - \nu} \left(\frac{x_b - \nu}{x_b - u} - \frac{x_a - \nu}{x_a - u}\right)}$$

$$= k(\mu - \nu)^2 \frac{(\beta - \alpha)}{\ln \frac{\beta(\alpha - 1)}{\alpha(\beta - 1)}},$$
(7)

5

4

$$6 \qquad h = k\omega^2 \chi \tag{8}$$

In order to determine the value of parameter  $\chi$ , the relationship among  $\chi$ ,  $\alpha$ ,  $\beta$  is 7 displayed in figure 3b. The dash line in figure 3a is the profile of the diagonal in 8 9 figure 3b, which represents that the sum of  $\alpha$  and  $\beta$  is 1. Parameter  $\chi$  changes little 10 when the location parameter varies in a certain range as marked with warm color in figure 3b. It means that the closer the points (A and B) are to the middle point, the 11 12 more significant the linear feature is. Then, the process between point A and point B13 can represent the whole transition process as shown in figure 3c. It is noted that the 14 transition process is symmetrical about the middle point approximately. Thus, we 15 assume that point A and point B are symmetrical about the middle point, and the sum of  $\alpha$  and  $\beta$  is 1. The change of parameter  $\chi$  is only related to parameter  $\alpha$  (or parameter 16  $\beta$ ), as shown in the diagonals in figure 3b (also in figure 3a). Parameter  $\chi$  changes 17 18 little when parameter  $\alpha$  is about 0.2 or larger. In figure 3c, three different situations 19 are carried out to study the influence of parameter  $\alpha$  on parameter  $\gamma$ . In each situation, 20 points (A and B) are set to be different positions, and their parameters were calculated 21 respectively in table 1. The parameters  $\alpha$  are set as 0.20, 0.25, 0.15 respectively in 22 three different situations marked with S1, S2 and S3. For S2 and S3, both of the percentages of  $\alpha$  changing to S1 are 25%, while the percentages of  $\chi$  changing are 23 only 5.15% and 6.76% respectively, which means the percentage change of  $\chi$  is much 24 less than  $\alpha$ . In addition, linear trends of these three ideal models are calculated 25 according to the points and by regression method which are marked as  $h_0$  in table 1. 26

The linear trends are also calculated by the values of point A and point B with Eq(5) which are marked as h in table 1. It is noted that although the positions of points are different, the trend obtained according to the points is almost the same as that obtained by regression method. The error percentages are 2.36%, 2.25%, 1.38% respectively, which means that we don't have to know the exactly positions of point A and B (the values of parameters  $\alpha$  and  $\beta$ ). We can approximate the value of  $\chi$ . Thus, in the following sections parameter  $\alpha$  is set as 0.2, and parameter  $\chi$  is 0.2164

8

#### 2.2 The prediction method of transition process

9 Eq. (8) shows the quantitative relationship among linear trend, instability 10 parameter, and amplitude of change. There is a linear relationship between linear trend and instability parameter; and there is the quadratic function relationship 11 12 between linear trend and amplitude of change. We did reveal this quantitative relationship much more than in theory but in real time series (Yan et al, 2016). Based 13 14 on this relationship, we are going to create a new method to deal with the problem that the transition process has not finished. During the real time sequence, the system 15 transits away from the original state, but it has not reached to a new state as shown in 16 figure 4. The red line represents the period which has been experienced, while the 17 18 gray line represents the period which has not been experienced. Based on the system 19 states which are far away from the original state, a quasi linear extension of the transition process is established (dash line). Then the parameters v and h are obtained 20 by Eq. (4). Assuming that the parameter k satisfies the statistics in the history of the 21 system, the parameter u can be predicted by Eq. (8), and the end moment is also 22 23 predicted.

24 
$$\begin{cases} x_t = x_{t-1} + kt(x_t - u)(v - x_t) \\ x'_t = x_t + \eta_t \end{cases}$$
 (9)

As shown in figure 5, four ideal time sequences are constructed by using the logistic model and random numbers as Eq. (9), where  $\eta_t$  represents the random number. An entire time sequence with 500 moments is shown in figure 5a and three other lengths of time sequences are shown in figures 5b, 5c and 5d respectively. The

parameters v, u and k of the logistic model are set as -1.0, 2.0, 0.1, for the ideal time 1 sequence, and the random number is limited in 0-1. The parameters v, h are obtained 2 by regression method before making prediction. It has to be noted that in this ideal 3 time sequence there is just one abrupt change, which means that we have no way to 4 obtain the value of the parameter k by counting many changes. Thus parameter k is 5 given directly, and the prediction of the end state (moment) is drawn in figure 5b, 5c 6 and 5d. For the entire time sequence, there are 500 moments as shown in figure 5a. In 7 8 figure 5b, only 240 moments are given, and the other moments are unknown. Then, 9 we obtain parameters v and h by regression method. The parameter u is calculated with Eq. (8). The blue line represents the prediction result. The transition process 10 would be ended in moment 342 with the end state value 2.92. In figure 5c, the end 11 12 moment and end state are predicted to be 356 and 2.65 respectively when the time sequence is given 250 moments. In figure 5d, the time sequence is given 260 13 moments. The end moment and end state are predicted to be 359 and 2.58 respectively. 14 The end moment and the end state of the prediction result match the presetting lines. 15 16 The results also show that the longer the transition process experience, the more accurate the prediction. 17

#### 18 **3. Results**

19 In order to test the validity of this prediction method in a real climate system, we apply this method to predict the uncompleted transition process of the PDO. The PDO 20 21 index data used is from website of the University of Washington (http://research.jisao.washington.edu/pdo/). The time period from January of 1900 to 22 November of 2015 is studied as the training data, and the time period from December 23 of 2015 to April of 2017 is used as the test data. During the following research, a 24 transition process starting from 2011 is studied. According to the prediction method, 25 26 several parameters have to be determined in advance. We first determine parameter k .

#### 1 **3.1 Threshold of parameter** *k*

2 Parameter k characterizes the stability of the system during climate change, which means that we can get the value of parameter k by counting all abrupt changes 3 of the PDO index. The histogram in Figure 6a shows the PDO time sequence from 4 January of 1900 to November of 2015, and it shows that the PDO went through 5 several changes. The green dots in Figure 6a are parameter k when the sub-sequence 6 7 length takes 20 years. In the early 1940s and late 1970s, there are two main transitions of the PDO. The absolute value of the parameter k is large, which means that the 8 9 system is much more unstable during this two transition processes. In the 1940s, the 10 PDO transits from a positive phase to a negative phase, and k < 0, whereas the 11 situation in the 1970s is the opposite. Figure 6b shows more k values corresponding to 12 the different sub-sequence lengths (as indicated by X-axis, the variation range of the sub-sequence is 20-60 years, with an interval of 1 year). The Y-axis is the start 13 14 moment, and the locations of the dots indicate the start moments for the 15 corresponding sub-sequence lengths. In particular, the blue dots represent that parameter k is negative, and the red dots represent that it is positive. There are more 16 dots in the left side region than in the right side region in figure 6. This is because 17 when the length of sub-sequence is short, the amplitude is also often small. More 18 19 transition processes are detected. When the length of the sub-sequence reaches or 20 exceeds 50 years, the transition change mainly begin in the 1940s and 1970s, which are also investigated in other research (Shi et al, 2014). The transition processes in 21 these two periods correspond to large k values, which means that these two transition 22 processes are more unstable than others. More statistical results indicate that the 23 threshold distribution of parameter k values in historical transition processes exhibit 24 multiple peaks (Figure 7). Specifically, the highest peak with the largest probability is 25 located near to 0. The k value is small, which indicates that the abrupt changes are 26 27 stable. There are some peaks on the left side and right side of zero. When k < 0, the 28 PDO time sequence transits from the positive phase to the negative phase, which the threshold of the k peak is wide and the probability is small; when k>0, the PDO time 29

sequence transits from the negative phase to the positive phase, which the threshold of 1 the k value is narrow and the probability is large. This indicates that the two 2 transitions, which one of them is that the system changes from the positive phase to 3 the negative phase, and the other is that the system changes from the negative phase to 4 the positive phase, are not symmetric, and the latter is more stable. Because there is a 5 difference in parameter k when the selected sub-sequence length is different, Figure 7 6 also shows the statistical properties of parameter k when the sub-sequence length is 20, 7 8 30, 40, 50, or 60 years. When the length of the sub-sequence is 20 years and 30 years, 9 there is only one main peak in the distribution of k values, and the parameter k value of the peak is about 0, which means that the transition change is more stable than the 10 other situations. When the length of the sub-sequence is 40, 50, or 60 years, there are 11 12 two main peaks. The peak value on the side of k>0 is not considerably different, which indicates that the stability degree of the transition change from negative to 13 positive is consistent; the location of the peak value on the side of k < 0 moves to the 14 left as the sub-sequence length increases, which means that the sub-sequence is longer, 15 16 the amplitude of detected transition change is larger, and it is more unstable. From the perspective of the value, a k value in the range of (-10, 10) accounts for 80.2% of all k 17 18 values, a k value in the range of (-5, 5) accounts for 74.2%, and a k value in the range 19 of (-2, 2) accounts for 58.6%. In the following studies, the k value is mainly set in the 20 range of (-2, 2).

#### 21 **3.2 Values of the initial state v and linear trend h**

We use the method proposed in section 2.2 to analyze the transition changes of the PDO. With different lengths of sub-sequences, three climate changes are detected to start from 1976, 2007 and 2011 respectively. In figure 8, the transition changes starting from 2007 and 2011 are shown, while the transition process starting from 1976 has not been shown. In table 2, parameters v and h are obtained by regression method for the transition processes starting from 2007 and 2011. When the length of sub-sequence is 10 years or 20 years, only the transition process starting from 2011 is

detected as shown in figure 8a and figure 8b. The parameter v is calculated with the 1 sequence before 2011. Then, the linear trend parameter h is calculated with the 2 segment after 2011. For the transition process starting from 2011, the values of initial 3 state were detected to be -0.45 and -0.03 when the length of sub-sequence is 10 years 4 or 20 years respectively, and both the linear trends are 1.054/month. When the lengths 5 of sub-sequences are set as 30 and 40 years, the transition process began in 2007 as 6 shown in figure 8c and figure 8d, and the values of initial state are 0.36 and 0.41, 7 8 respectively, with an linear trend of 0.227/month. When we detect the transition 9 process in a sub-sequence, the percentile threshold method (Huang, 1990) is used. Then, a transition process in the sub-sequence is detected (Yan et al, 2015, 2016). The 10 change with the largest amplitude will be detected. The start moment of the transition 11 12 change is identified to be 2011 as shown in table 2.

In figure 8, it is noted that the PDO time sequence is leaving the stable state from 13 the start moment. The transition change occurs over a period of time, which is called 14 the transition process. When the transition process has not finished, it appears to be 15 16 increasing part. In order to detect whether there are other transition processes, we change the length of the sub-sequences to yearly intervals. That is, the sub-sequence 17 length is set as 10, 11, 12, ..., up to 60 years. Then, the initial state v and the linear 18 trend h of these transition processes are obtained as shown in figure 9. When the 19 20 sub-sequence length is set less than approximately 40 years, the transition processes are detected only twice. One began in 2007, and the other began in 2011. The value of 21 parameter h is unchangeable nearly for each transition process, while the value of 22 parameter v is changing when the length of sub-sequence is different. In particular, the 23 24 transition process starting from 2007 is detected for the sub-sequences of about 30-40 years, and the value of parameter v is in the range of (0.28, 0.45). The transition 25 process starting from 2011 is detected for the sub-sequences of about 10-30 years, and 26 the value of parameter v increases as the length of the sub-sequence increases, 27 whereas the variation range of parameter v is (-0.48, 0.12), which is significantly 28 29 different from the situation of the transition process starting from 2007.

# 3.3 Prediction of the uncompleted transition process beginning in 2011

3 After the threshold ranges for parameters k, v, and h are determined, according to the quantitative relationship, we can calculate the end state and the end moment of the 4 transition process. Using the transition process in 2011 as an example, we study the 5 6 ending state and end moment for the PDO index transition process. According to the research results that are presented in Sections 3.1 and 3.2, the parameter is 7 8 h=1.054/month in this transition process, and the threshold range of parameter k is 9 determined to be (0, 2). The range of parameter v is determined to be (-0.48, 0.12), and the variation situation of parameter u and end moment with parameters k and v10 11 are shown in Figure 10. The results indicate that the threshold range of parameter u12 for the ending state is (1, 7), and the time range of the ending moment is (2013, 2017). 13 According to the probability of parameter k, the end moment of this transition process 14 is about 2015, and after that time, the sequence stops to increase, approaching to a 15 stable state with value of 1.6.

In figure 11, a sketch map is displayed to briefly explain how the prediction 16 method works. The PDO time sequence is displayed as a black line. The period during 17 2006~2011 is detected as the initial state, and a transition process is increasing from 18 19 this initial state. It is not able to be known whether the increasing process has been completed or not. Based on the linear regression method, the initial state and the 20 linear trend are obtained and shown as purple dash lines. Then by the method 21 proposed in section 2.2, all possible end states of this transition process are obtained 22 with Eq. (8) as shown in figure 10, and the most likely end state is marked as a green 23 24 dash line.. Unlike the uncompleted transition process of ideal experiment, the 25 transition process has completed in about 2015 since we detected the PDO change in 2016. This transition process started from 2011 and ends in 2015. The initial moment 26 27 and the end moment are marked as black dash lines. However, we are still not sure whether the PDO finish this transition process completely or not for it it appears at the 28

end of the sequence. Many statistical methods are not accurate for the detecting both
ends of the sequence. Thus, the real PDO sequence during 2016~2017 is added to the
end of the PDO time sequence. The PDO value from 2015 to 2017 is almost
unchanged, which is consistent with the predicted result.

5

### 4. Conclusion and discussion

A novel method had been proposed to identify the transition process of climate 6 7 change in our previous research. By defining initial state parameter v, linear trend parameter h, end state parameter u, and instability parameter k, a quantitative 8 relationship among these parameters was revealed. Based on the relationship, we 9 10 develop a method to study uncompleted transition processes. The method is applied to predict ideal time sequences and the PDO time sequence. In the ideal experiments, 11 12 three different time sequences with different length are constructed. Based on the initial state and the linear trend which the system had experienced, and the given 13 14 parameter, the end state and end moment of the transition process are predicted. The 15 prediction result does match the ideal time sequence well. For the PDO time sequence, a transition change beginning in 2011 was taken to test the prediction method. The 16 17 end moment of this transition process is predicted to be 2015. which is consistent with 18 the real time sequence.

In this prediction method, the quantitative relationship among the parameters characterizing the transition process is vital. According to the segment of the transition process which has been occurred, we determine the parameters and predict the end moment and the end state. In fact, this is also a extrapolation method. It is noted that the uncompleted climate change we studied is closed to the end of the sequence. Due to the lack of enough data, it is difficult to study the end of time sequence by using other statistical methods.

#### 1 Table1. The parameters of ideal models

Situations	α	χ	h0	h	<i>h0-h</i>  / <i>h</i>
S1	0.20	21.64E-2	12.99E-4	12.69E-4	2.36%
S2	0.25	22.76E-2	9.10E-4	8.90E-4	2.25%
S3	0.15	20.18E-2	32.27E-4	32.72E-4	1.38%

#### 2 Table2. Parameters *v* and *h* obtained with different sub-sequences

Length of sub-sequence	Start moment (year.month)	v	h (month <sup>-1</sup> )
10a	2011.06	-0.45	1.054
20a	2011.06	-0.03	1.054
30a	2007.11	0.36	0.227
40a	2007.11	0.41	0.227

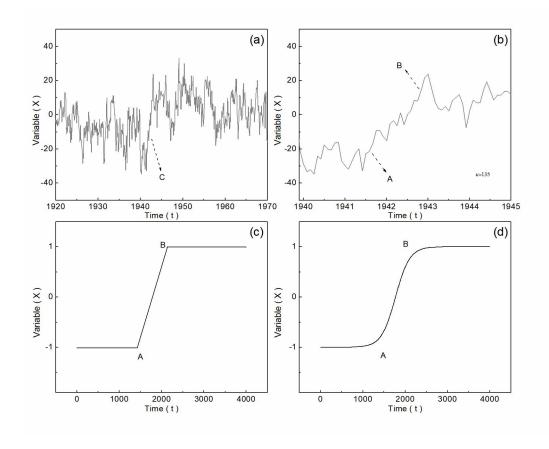

Figure 1. Transition process of abrupt change in real time sequence and ideal time sequence. (a) The PDO time sequence during 1920 to 1970; (b) The PDO time sequence during 1940 to 1945; (c) The transition process presented by piece-wise function; (d) The transition process presented by continuous function

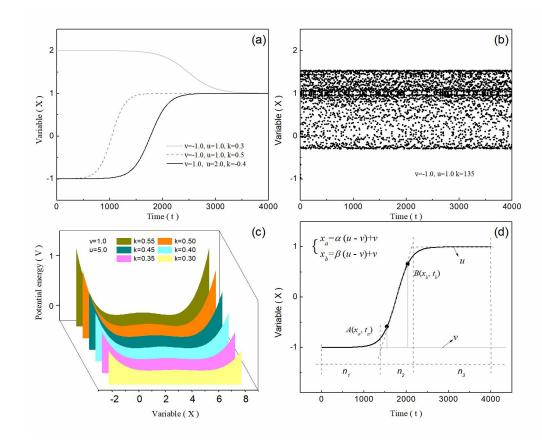

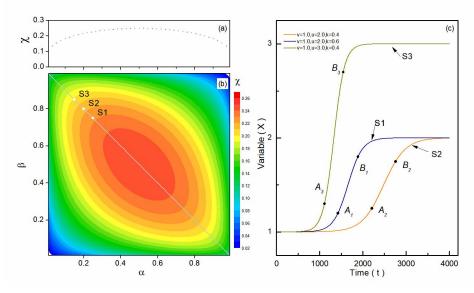

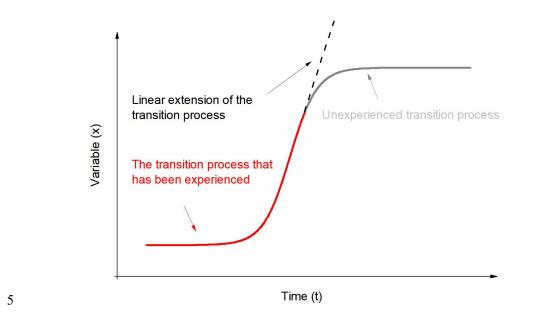

Figure 2. The system presented by Eq. (2). (a)The transition processes of system swinging between different stable states since the parameters are different; (b)The system stays in unstable states; (c)The generalized potential energy function of system performs differently since the parameters are different; (d)Different segments of the transition process in the ideal time sequence and the system states x expressed with location parameters.

- 1 Figure 3. The influence of different value of parameters  $\alpha$  and  $\beta$  on parameter  $\chi$  and
- 2 parameter h. (a) Diagonal section of parameter  $\chi$  in figure b (gray line); (b) Parameter
- 3  $\chi$  with location parameters  $\alpha$  and  $\beta$ ; (c)Points A and B stay in different positions in
- 4 three situations marked as S1, S2, S3.

6 Figure 4. The schematic diagram of prediction method.

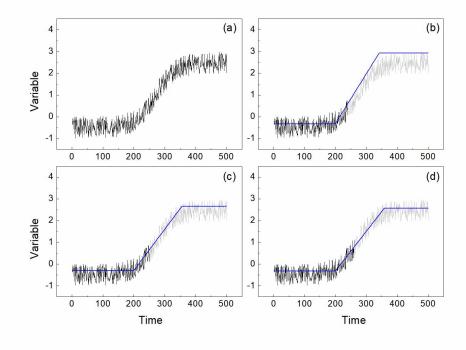

Figure 5. The ideal time sequence constructed by the logistic model and random
numbers. (a) Completed transition process with 500 moments, Uncompleted transition
processes (the gray lines) and their prediction result (the blue lines) with (b) 240

1 moments, (c) 250 moments, and (d) 260 moments, the light gray lines are the original

2 entire ideal time sequences.

3

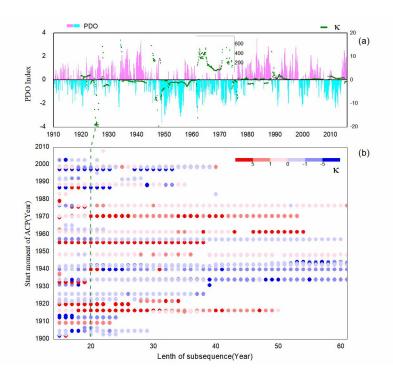

Figure 6. Identification of the PDO time sequence and instability parameter k with 4 different sub-sequence lengths. (a) The X-axis is the year, the histogram in the figure 5 shows the PDO time sequence (left Y-axis), and the green dots indicate the value of 6 parameter k when the sub-sequence is 20 years (right Y-axis); (b) the start moments of 7 transition processes with different sub-sequence lengths (the red color dots represent 8 increasing processes, and blue color dots represent decreasing changes, with deeper 9 colors representing higher values). The X-axis is the sub-sequence length (month), 10 and the Y-axis is the start moment of abrupt change (year). 11

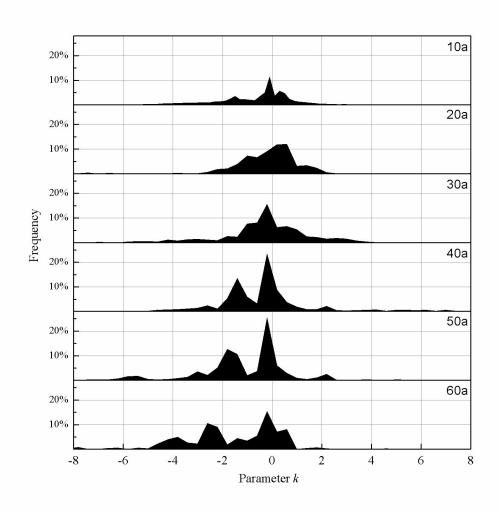

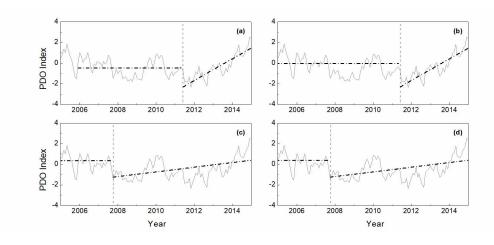

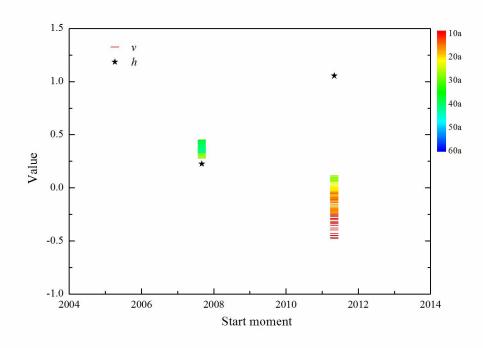

Figure 7. Statistical results of instability parameters for different sub-sequences
lengths. The X-axis is the value of the parameter, and the Y-axis is the statistical
frequency with a sub-sequence length of 10 years. The gray region in the upper-right
corner is for the sub-sequence of 20-60 years.

7 Figure 8. The PDO time sequences and the detection of parameters v and h when the

sub-sequence was set as (a)10 years, (b)20 years, (c)30 years, (d)40 years. The gray lines represent the PDO time sequence. The horizontal dash lines represent initial states, the slope dash lines represent linear trend lines of the transition process, and vertical dotted lines represent the start moment.

5

6 Figure 9. The values of the parameters v and k of two transition processes with 7 different lengths of sub-sequence. The black stars represent the values of parameter h, 8 and the colourful short bar represent the values of parameter v. The colour bar 9 represents years of the sub-sequence length from 10 to 60 in intervals of 1.

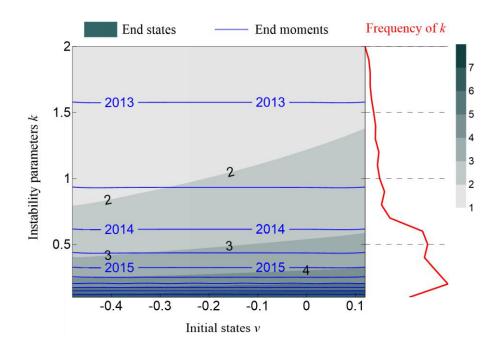

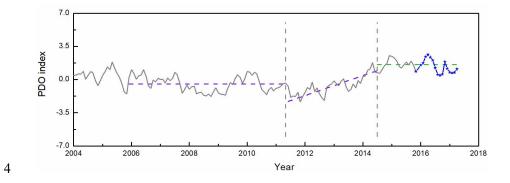

Figure 10. Variation end state and end moment with the initial state parameter v(horizontal ordinate) and instability parameter k (vertical coordinate). The red line on

3 the right side shows the probability distribution of instability parameter k.

5 Figure 11. Prediction of the PDO index. The gray line represents the PDO index 6 before 2015; the blue line represents the PDO index after 2015; the gray dash line

before 2015; the blue line represents the PDO index after 2015; the gray dash line
represent the start moment and end moment; the purple dash lines represent the initial

8 state and the linear trend line, the green line represent the prediction end state.
