6 **Abstract.** In this paper, a regional study of the mode-2 internal solitary waves (ISWs) in the Pacific coast of Central
7 America is carried out by using seismic reflection method. The observed relationship between the dimensionless phase
8 velocity and the dimensionless amplitude (DA) of the mode-2 ISWs was analysed. When $DA < 1$, the dimensionless phase
9 velocity increases with the increasing dimensionless amplitude, divided into two parts with different growth rates. When
10 $DA > 1$, the dimensionless phase velocity increases with the increasing dimensionless amplitude at a relatively small growth
11 rate. We suggest that the influences of seawater depth (submarine topography), pycnocline depth, and pycnocline thickness
12 on the phase velocity of the mode-2 ISWs in the study area, cause the relationship between the dimensionless phase velocity
13 and the dimensionless amplitude diversified. The observed relationship between the dimensionless wavelength and the
14 dimensionless amplitude of the mode-2 ISWs was also analysed. When $DA < 1$ and $DA > 2$, the dimensionless wavelength
15 decreases and increases with the increasing dimensionless amplitude, respectively. Additionally, the seawater depth has a
16 great influence on the wavelength of the mode-2 ISWs in the study area, and overall the wavelength increases with the
17 increasing seawater depth. As for the vertical structure of the amplitude of the mode-2 ISWs in the study area, we find that it
18 is affected by the nonlinearity of the ISWs and the pycnocline deviation (especially the downward pycnocline deviation).

19 1 Introduction

20 The amplitude and propagation velocity of the mode-1 ISWs are larger than those in the mode-2 ISWs. The mode-1
21 ISWs are more common in the ocean. In recent years, with the advancement of observation instruments, the mode-2 ISWs in
22 the ocean have been gradually observed, such as on the New Jersey shelf (Shroyer et al., 2010), in the South China Sea (Liu
23 et al., 2013; Ramp et al., 2015; Yang et al., 2009), at Georges Bank (Bogucki et al., 2005), over Mascarene Ridge in Indian
24 Ocean (Da Silva et al., 2011)), and on the Australian North West Shelf (Rayson et al., 2019). Conventional physical
25 oceanography observation and remote sensing observation have spatial resolution limitations. That is, the horizontal
26 resolution of conventional physical oceanography observation methods (such as mooring) is low, and the vertical resolution
27 of remote sensing observations is low. Seismic oceanography (Holbrook et al., 2003; Ruddick et al., 2009), as a new
28 oceanography survey method, has high spatial resolution (the vertical resolution and horizontal resolution can reach about
29 10m). It can better describe the spatial structure and related characteristics of mesoscale and small scale phenomena in the

30 ocean (Biescas et al., 2008, 2010; Fer et al., 2010; Holbrook & Fer, 2005; Holbrook et al., 2013; Pinheiro et al., 2010;
31 Sallares et al., 2016; Sheen et al., 2009; Tsuji et al., 2005). Scholars have used seismic oceanography method to carry out
32 related studies on the geometry and kinematics characteristics of ISWs in the South China Sea, the Mediterranean Sea and
33 the Pacific Coast of Central America (Bai et al., 2017; Fan et al., 2021a, 2021b; Geng et al., 2019; Sun et al., 2019; Tang et
34 al., 2014, 2018).

35 At present, the researches on the mode-2 ISWs in the ocean are mainly based on simulation. Through simulation,
36 scholars have found that the pycnocline deviation will affect the stability of the mode-2 ISWs, making the top and bottom
37 structure of the mode-2 ISWs asymmetrical (Carr et al., 2015; Cheng et al., 2018; Olsthoorn et al., 2013). The instability
38 caused by the pycnocline deviation mainly appears at the bottom of the mode-2 ISWs, is manifested in that the amplitude of
39 the mode-2 ISWs peak is smaller than the amplitude of the trough, because the upper sea layer is thinner than the bottom sea
40 layer. The wave tail will appear similar to K-H instability billow and the wave core will appear small-scale flip (Carr et al.,
41 2015; Cheng et al., 2018). For the phase velocity of the mode-2 ISWs, scholars found through simulation experiments that it
42 increases with the increasing amplitude (Maxworthy, 1983; Salloum et al., 2012; Stamp & Jacka, 1995; Terez & Knio,
43 1998). Brandt et al. (2014) simulated the material transport of mode-2 ISWs with large amplitude in the laboratory. They
44 found that, when $2a/h_2 > 4$ (a is the amplitude of the mode-2 ISWs and h_2 is the pycnocline thickness), the linear relationship
45 between the phase velocity (wavelength) and the amplitude is destroyed. That is, when the amplitude $2a/h_2 \geq 4$, the phase
46 velocity increases relatively slowly, and the wavelength increases rapidly. They believe that the above results are caused by
47 strong internal circulation related to the very large amplitude and the influence of the top and bottom boundaries. Chen et al.
48 (2014) calculated the KdV phase velocity and the fully nonlinear phase velocity of the ISWs as the function of the
49 pycnocline depth and the pycnocline thickness, respectively. They found the phase velocity of the mode-2 ISWs increases
50 monotonously with the increasing pycnocline depth, and firstly increases and then decreases with the increasing pycnocline
51 thickness. Carr et al. (2015) found by simulations that the pycnocline deviation has little effect on the phase velocity,
52 wavelength, and amplitude of the mode-2 ISWs. Maderich et al. (2015) found that for the mode-2 ISWs, when the
53 dimensionless amplitude $2a/h_2 < 1$, the deep water weakly nonlinear theory (Benjamin, 1967) can describe the numerical
54 simulation and experimental simulation results well. When $2a/h_2 > 1$, the wavelength (phase velocity) increases with the
55 amplitude faster than the results predicted by the deep water weakly nonlinear theory. But the solution of Kozlov and
56 Makarov (1990) can well estimate the corresponding wavelength and phase velocity when the amplitude is $1 < 2a/h_2 < 5$.
57 Terletska et al. (2016) found that the phase velocity and amplitude of the mode-2 ISWs will decrease after passing the step.
58 And the closer the mode-2 ISWs is to the step in the vertical direction at the time of incidence, the smaller the phase velocity
59 and amplitude of the mode-2 ISWs after passing the step. Kurkina et al. (2017) used GDEM (Generalized Digital
60 Environmental Model) to find that the seawater depth in the South China Sea is the main controlling factor of the mode-2
61 ISWs phase velocity, and the phase velocity increases exponentially with the increasing seawater depth. Deepwell et al.
62 (2019) found by simulation that the relationship curve that the mode-2 ISWs phase velocity increases with the increasing

63 amplitude has a strong quadratic fitting relationship. They speculated that this quadratic fitting relationship comes from the
64 influence of seawater depth (when the seawater depth is smaller, the phase velocity is also smaller).

65 The simulation can well reveal the kinematics characteristics of the mode-2 ISWs, but the actual ocean conditions are
66 often more complicated, which is manifested by the diversity of controlling factors in the kinematics process. The
67 observations including seismic oceanography method are also required to continually provide basic understanding of the
68 geometry and kinematics characteristics of the mode-2 ISWs. For example, limited by factors such as the lower spatial
69 resolution of the observation methods, previous scholars have less direct observation research on the phase velocity and
70 wavelength of the mode-2 ISWs in the ocean. And there is even less research (including observation research) on the vertical
71 structure of the mode-2 ISWs. The seismic oceanography method has more advantages for carrying out the above-mentioned
72 research due to its higher spatial resolution. The Pacific coast of Central America (western Nicaragua) has relatively
73 continuous submarine topography along the coastline, including continental shelf and continental slope, with the seawater
74 depth of 100-2000m (Fig. 1). At present, there is relatively little research work on internal waves in this area. We
75 reprocessed the historical seismic data in this area and identified a large number of mode-2 ISWs with relatively complete
76 spatial structures in the region. This discovery is very helpful to carry out observation research on the geometry and
77 kinematics characteristics of the mode-2 ISWs. Fan et al. (2021a, 2021b) used the multichannel seismic data of the survey
78 lines L88 and L76 (cruise EW0412, see Fig. 1 for the survey line locations) in the Pacific coast of Central America to
79 respectively report the mode-2 ISWs in this area and study the shoaling features of the mode-2 ISWs in this area. However, a
80 single survey line can only reveal the local characteristics of the mode-2 ISWs in the study area. Deep understanding of the
81 geometry and kinematics characteristics of the mode-2 ISWs in the study area requires a regional systematic study. In this
82 work, we reprocessed the seismic data of the entire study area, and identified numerous mode-2 ISWs on multiple survey
83 lines in the region (the positions of the observed ISWs and the survey lines they located are shown by the black filled circles
84 and the red lines in Fig. 1, respectively). Based on the numerous mode-2 ISWs observed by multiple survey lines in the study
85 area, this paper will conduct a regional study on the characteristic parameters such as the pycnocline deviation degree, phase
86 velocity, and wavelength of the mode-2 ISWs, as well as the vertical structure characteristics of the mode-2 ISWs' amplitude
87 in the study area.

88

107 thickness, and the equivalent wavelength of the mode-2 ISWs. For the mode-2 ISWs with a multilayer structure, the sum of
108 all ISWs peak amplitudes a_p and the sum of all ISWs trough amplitudes a_t are respectively taken as the equivalent peak and
109 trough amplitude of the mode-2 ISWs with a three-layer model structure. Then the equivalent amplitude of the mode-2 ISWs
110 with a three-layer model structure is the average of a_p and a_t , and the equivalent pycnocline thickness is calculated by $h_2=h-$
111 a_p-a_t , where h is the seawater thickness affected by the mode-2 ISWs with a multilayer structure. The equivalent wavelength
112 of the mode-2 ISWs with a three-layer model structure is the average of all ISWs peak and trough wavelengths in the
113 multilayer structure. The detailed calculation process is described in Fan et al. (2021a). This study uses an improved ISWs
114 apparent phase velocity calculation method to calculate the apparent phase velocity of ISWs. This method firstly does pre-
115 stack migration of the common offset gather sections, and then pick the CMP and shot point pairs corresponding to the ISWs
116 trough or peak from the pre-stack migration sections of different offset with high signal-to-noise ratio. By fitting the CMP-
117 shot point pairs, we can calculate the apparent phase velocity and apparent propagation direction of the ISWs. The ISWs
118 horizontal velocity can be expressed by $v=(cmp2-cmp1)/T=(cmp2-cmp1)/[(s2-s1)*dt]$, where $cmp1$ and $cmp2$ are the peak or
119 trough positions of the ISWs at different time, $s1$ and $s2$ are the shot numbers corresponding to $cmp1$ and $cmp2$, and dt is the
120 time interval of shots. The detailed calculation process is described in Fan et al. (2021a).

121 The wavelength of the mode-2 ISWs is usually defined as half-width at half-amplitude of the ISWs (Carr et al., 2015;
122 Stamp & Jacka, 1995), as shown by λ in Fig. 2. Since the ISWs move in the horizontal direction during the seismic
123 acquisition process, the wavelength of the ISWs observed by the seismic reflection method is the apparent wavelength. The
124 apparent wavelength of the ISWs is controlled by the relative motion direction of the ship and the ISWs, the ship speed, and
125 the propagation speed of the ISWs. The propagation speed of the mode-2 ISWs (about 0.5m/s) is generally lower than the
126 ship speed (about 2.5m/s) during seismic acquisition. When correcting the apparent wavelength of the ISWs to obtain the
127 actual wavelength, it is divided into two situations in which the motion direction of the ISWs and the ship is the same and
128 opposite, as shown in Fig. 2. When the ISWs and the ship move in the same direction, the wavelength (apparent wavelength)
129 estimated from the seismic stacked section is larger. That is, the wavelength (apparent wavelength λ_s) of the ISWs observed
130 on the seismic stacked section denoted by the blue curve in Fig. 2a is greater than the wavelength λ of the actual ISWs at the
131 beginning and end respectively denoted by the black and red curves in Fig. 2a. In order to eliminate the influence of the
132 horizontal movement of the ISWs, when correcting the apparent wavelength λ_s to obtain the actual wavelength λ , it is
133 necessary to subtract the distance x_w moved by the ISWs within the seismic acquisition time corresponding to the apparent
134 wavelength distance of the ISWs. That is:

$$135 \quad \lambda = \lambda_s - x_w = \lambda_s - \lambda_s / V_{ship} * V_{water} \quad (1)$$

136 where V_{ship} is the ship speed, and V_{water} is the propagation speed of the ISWs (Fig. 2a).

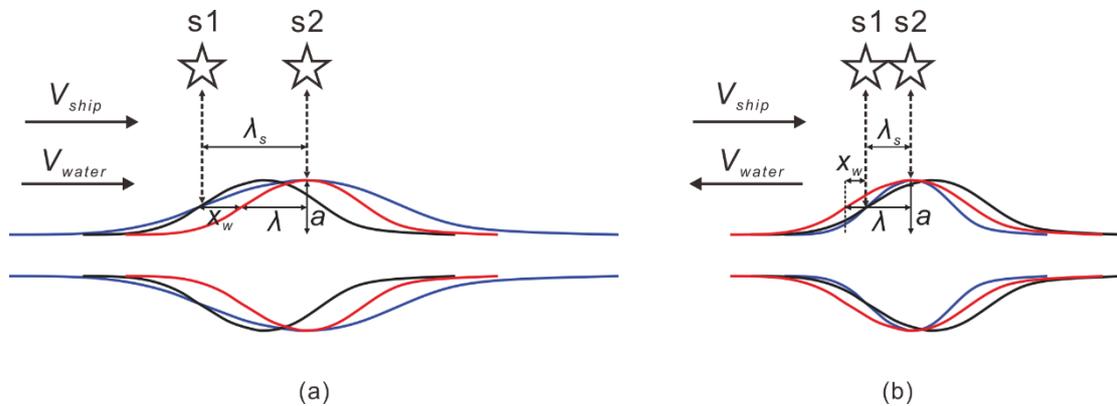

137 When the ISWs and the ship move in the opposite direction, the wavelength (apparent wavelength) estimated from the
138 seismic stacked section is smaller. That is, the wavelength (apparent wavelength λ_s) of the ISWs observed on the seismic
139 stacked section denoted by the blue curve in Fig. 2b is smaller than the wavelength λ of the actual ISWs at the beginning and
140 end respectively denoted by the black and red curves in Fig. 2b. In order to eliminate the influence of the horizontal

141 movement of the ISWs, when correcting the apparent wavelength λ_s to obtain the actual wavelength λ , it is necessary to add
 142 the distance x_w moved by the ISWs within the seismic acquisition time corresponding to the apparent wavelength distance of
 143 the ISWs. That is:

$$144 \quad \lambda = \lambda_s + x_w = \lambda_s + \lambda_s / V_{ship} * V_{water} \quad (2)$$

145 where V_{ship} is the ship speed, and V_{water} is the propagation speed of the ISWs (Fig. 2b).

156 3 Results and Interpretations

157 3.1 Typical Sections Interpretation and Regional Distribution Characteristics of the Mode-2 ISWs

158 In addition to the survey lines L88 and L76 with mode-2 ISWs observed by Fan et al. (2021a, 2021b), we also found
 159 mode-2 ISWs on many other survey lines in the study area. Two typical survey lines are L84 and L74 (see the red lines in
 160 Fig. 1 for the locations of these two survey lines). Figure 3 shows the partial seismic stacked section S1 of the survey line
 161 L84 (see the blue line in Fig. 1 for the location of this section S1). We have identified 10 mode-2 ISWs from the seismic
 162 section S1 (see Fig. 3 for their positions and corresponding numbers. ISW1-ISW4 are located at the shelf break, and ISW5-
 163 ISW10 are located on the continental shelf), and calculated the characteristic parameters of these 10 mode-2 ISWs, such as
 164 the seafloor depth (seawater depth) H , maximum amplitude (in the vertical direction), equivalent amplitude a , equivalent
 165 pycnocline thickness h_2 , dimensionless amplitude $2a/h_2$, mid-depths of the pycnocline hc , the degree to which the mid-depth
 166 of the pycnocline deviates from 1/2 seafloor depth Op , equivalent wavelength λ , dimensionless wavelength $2\lambda/h_2$, and
 167 apparent phase velocity U_c (Table 1). The equivalent wavelength and the dimensionless wavelength in Table 1 have been

168 corrected using Eq. (1) (the ISWs have the same motion direction as the ship, and the ISWs with the large phase velocity
169 estimation error have been corrected using a phase velocity of 0.5m/s). The maximum amplitudes of the ISWs ISW1-ISW7
170 on the survey line L84 are all less than 10m, and the maximum amplitudes of ISW8-ISW10 are larger, around 15m. The
171 $2a/h_2$ values of these ten mode-2 ISWs on the survey line L84 are all less than 2, and they belong to the mode-2 ISWs with
172 small amplitude (Brandt et al., 2014). The $2a/h_2$ values of ISW8, ISW9, and ISW10 are around 1, and their amplitudes are
173 slightly larger in these small-amplitude mode-2 ISWs. When calculating the degree to which the mid-depth of the pycnocline
174 deviates from 1/2 seafloor depth, it is found that except for the pycnocline centres of ISW8, ISW9, and ISW10 are deeper
175 than 1/2 seafloor depths, the pycnocline centres of the other seven mode-2 ISWs are shallower than 1/2 seafloor depths. For
176 ISW1, ISW2, and ISW3, the degrees to which the mid-depth of the pycnocline deviates from 1/2 seafloor depth are both
177 greater than 20%, which appear as the asymmetry of waveforms (the asymmetry of the front and rear waveform, and the
178 asymmetry of the top and bottom waveform). When the degree to which the mid-depth of the pycnocline deviates from 1/2
179 seafloor depth is small, the waveform of the mode-2 ISWs is more symmetrical, such as ISW8, ISW9, and ISW10. The
180 waveforms of ISW1, ISW2, and ISW3 at the shelf break are asymmetrical, and their dimensionless wavelength $2\lambda/h_2$ is
181 significantly larger than the $2\lambda/h_2$ of the ISWs on the continental shelf which have the same level of dimensionless
182 amplitudes ($2a/h_2$) (for example, the $2a/h_2$ value of ISW2 is 0.45, and the value of $2\lambda/h_2$ is 9.55; the value of $2a/h_2$ of ISW7 is
183 0.42, and the value of $2\lambda/h_2$ is 3.49), making the overall relationship between dimensionless wavelength $2\lambda/h_2$ and the
184 dimensionless amplitude $2a/h_2$ are not absolute linear correlation (the dimensionless wavelength $2\lambda/h_2$ increases with the
185 increasing dimensionless amplitude). The apparent phase velocities of the 10 mode-2 ISWs on the survey line L84 are about
186 0.5 m/s, and the apparent propagation directions are all shoreward. For ISWs with small apparent phase velocity calculation
187 errors in shallow water (ISW6, ISW7, and ISW9), the apparent phase velocity does not strictly increase with the increasing
188 dimensionless amplitude $2a/h_2$. For example, the $2a/h_2$ value of ISW6 is 0.4, and the apparent phase velocity is about 0.58
189 m/s; The $2a/h_2$ value of ISW9 is 1.19, and the apparent phase velocity is about 0.38 m/s.

198 **Note.** H , seafloor depths. A , maximum amplitudes. a , equivalent ISWs amplitudes. h_2 , equivalent pycnocline thicknesses. hc , the
 199 mid-depths of the pycnocline. Op , the degree to which the mid-depth of the pycnocline deviates from 1/2 seafloor depth. λ ,
 200 equivalent wavelengths. U_c , apparent phase velocities obtained from seismic observation.

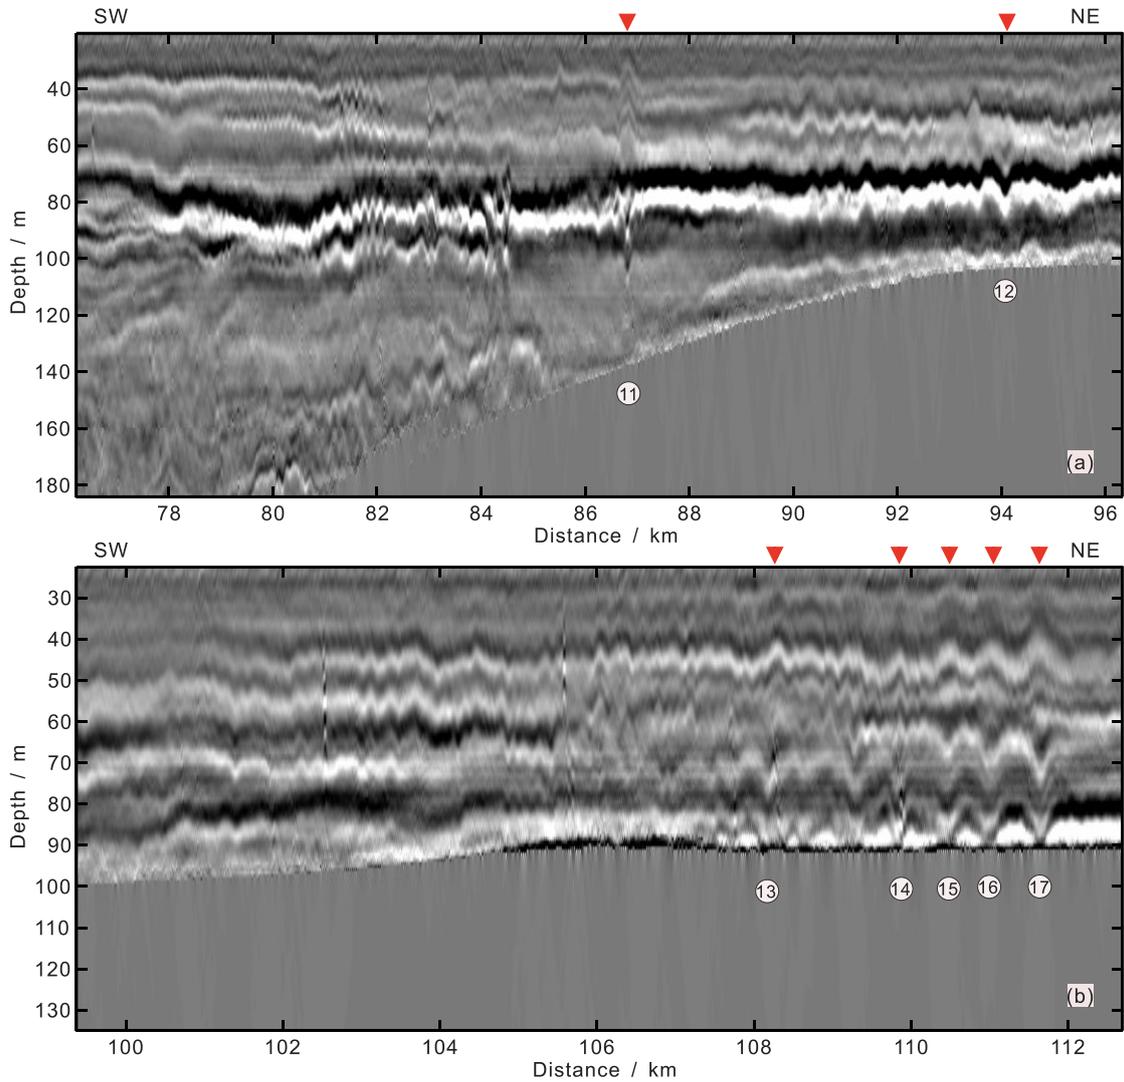

201

202

203 The survey line L74 is located in the southeast direction of the survey line L84 (see Fig. 1 for the specific location).
204 Figure 4 shows the partial seismic stacked sections (S2 and S3) of the survey line L74. We have identified seven mode-2
205 ISWs from the seismic sections S2 and S3. Their positions and corresponding numbers are shown in Fig. 4, and the
206 statistical characteristic parameters are shown in Table 2. The equivalent wavelength and the dimensionless wavelength in
207 Table 2 have been corrected using Eq. (1) (the ISWs have the same motion direction as the ship, and the ISWs with the large
208 phase velocity estimation error have been corrected using a phase velocity of 0.5 m/s). The maximum amplitudes of the
209 ISWs ISW12-ISW17 on the survey line L74 are all less than 10 m, and the maximum amplitude of ISW11 is larger, 13.6 m.
210 The $2a/h_2$ values of these seven mode-2 ISWs are all less than 2. They are the mode-2 ISWs with small amplitude, and the
211 amplitude of ISW11 is slightly larger among them. When calculating the degree to which the mid-depth of the pycnocline
212 deviates from $1/2$ seafloor depth, it is found that the pycnocline centres of the mode-2 ISWs ISW11-ISW17 are all deeper
213 than $1/2$ of the seafloor depths. Except for ISW11 (the bottom reflection event is broken), as for the other six mode-2 ISWs
214 ISW12-ISW17, the degrees to which the mid-depth of the pycnocline deviates from $1/2$ seafloor depth are both greater than
215 15%. The asymmetry of ISW12 and ISW13 is manifested in that the connection between the top peaks of the ISWs and the
216 bottom troughs of the ISWs is not vertical. The pycnocline centre of ISW14 deviates from $1/2$ of the seafloor depth the most,
217 which is 51.5%. Its asymmetry is manifested in the large difference between the top and bottom waveforms near the
218 pycnocline centre. ISW15, ISW16, and ISW17 are located on the continental shelf, and their pycnocline deviations are larger,
219 but the waveforms are more symmetrical than other ISWs. When the downward pycnocline deviation is large, the influence
220 of pycnocline deviation on the stability of the mode-2 ISWs is more complicated than when the pycnocline deviates upwards,
221 and it may be controlled by factors such as wavelength. There is no absolute linear correlation relationship between the
222 dimensionless wavelength $2\lambda/h_2$ and the dimensionless amplitude $2a/h_2$ of the seven mode-2 ISWs on the survey line L74
223 (the dimensionless wavelength $2\lambda/h_2$ increases with the increasing dimensionless amplitude $2a/h_2$). For example, the $2a/h_2$
224 values of ISW12 and ISW14 are greater than that of ISW16, but the dimensionless wavelength of ISW16 is greater than the
225 dimensionless wavelengths of ISW12 and ISW14. The apparent phase velocities of the seven mode-2 ISWs on the survey
226 line L74 are about 0.5 m/s, and their propagation directions are all shoreward. For the ISWs in shallow water where the
227 apparent phase velocity calculation errors are small (ISW12, ISW14, ISW16, and ISW17), the apparent phase velocity
228 generally increases with the increasing dimensionless amplitude $2a/h_2$.

240

241 In addition to the survey lines L74 and L84, the mode-2 ISWs also have sporadic distribution on other survey lines in
 242 the area (see the black filled circles in Fig. 1). We have identified 70 mode-2 ISWs in the study area. They appeared from 2
 243 December 2004 to 18 December 2004. On 17 December 2004 and 18 December 2004, there were more mode-2 ISWs (Fig.
 244 5a), 21 (10 for survey line L84, 6 for survey line L88, and 5 for survey line L76) and 9 (1 for survey line L72, 5 for survey
 245 line L76, and 3 for survey line L103) respectively. Observe the distribution of the appearance time of mode-2 ISWs observed
 246 in the study area in Fig. 5a (in days). It can be found that the mode-2 ISWs frequently appeared on the northwest side of the
 247 study area in December 2004, and appeared in early and late December. In addition, the spatial distribution range of the
 248 mode-2 ISWs is large, ranging from the continental slope to the continental shelf (see Figures 1, 3, and 4). Figure 5b shows
 249 the time when the mode-2 ISWs observed in the study area appeared in hours. Combined with Fig. 5a, it can be found that
 250 from 2 December 2004 to 8 December 2004, the ISWs appeared at around 12:00 and 00:00 (or 24:00) in a day; From 10
 251 December 2004 to 13 December 2004, the ISWs appeared at around 12:00 and 24:00 in a day, and relatively more appeared
 252 around 12:00; From 14 December 2004 to 18 December 2004, the ISWs appeared at around 12:00 and 00:00 (or 24:00) in a
 253 day, and relatively more appeared around 00:00 (or 24:00). The survey lines L103, L105, and L107 are perpendicular to the
 254 propagation direction of the mode-2 ISWs in the study area (Fig. 1). Therefore, these three survey lines are not included in
 255 the subsequent statistical analysis of the mode-2 ISWs characteristic parameters. We have counted the characteristic
 256 parameters of 53 mode-2 ISWs in the study area. In these 53 mode-2 ISWs, there are 51 small-amplitude ISWs ($2a/h_2 < 2$),
 257 and there are 40 ISWs with smaller amplitude ($2a/h_2 < 1$) among these 51 small-amplitude ISWs (Fig. 6a). The mode-2 ISWs
 258 in the study area are dominated by smaller amplitudes (Fig. 6a). The maximum amplitude (in the vertical direction) of the
 259 mode-2 ISWs mainly changes in the range of 3-13 m (Fig. 6d), and the equivalent wavelengths of most of the mode-2 ISWs
 260 are on the order of about 100 m (Fig. 6c, the equivalent wavelength in the figure has been corrected according to Eq. (1) and
 261 Eq. (2)). When calculating the phase velocity of the mode-2 ISWs, due to the low signal-to-noise ratio of some survey lines,
 262 the calculation errors of some ISWs phase velocities are relatively large. Therefore, when analysing the apparent phase
 263 velocity of the mode-2 ISWs of the study area, we only used 26 ISWs with relatively small errors (the error is less than half

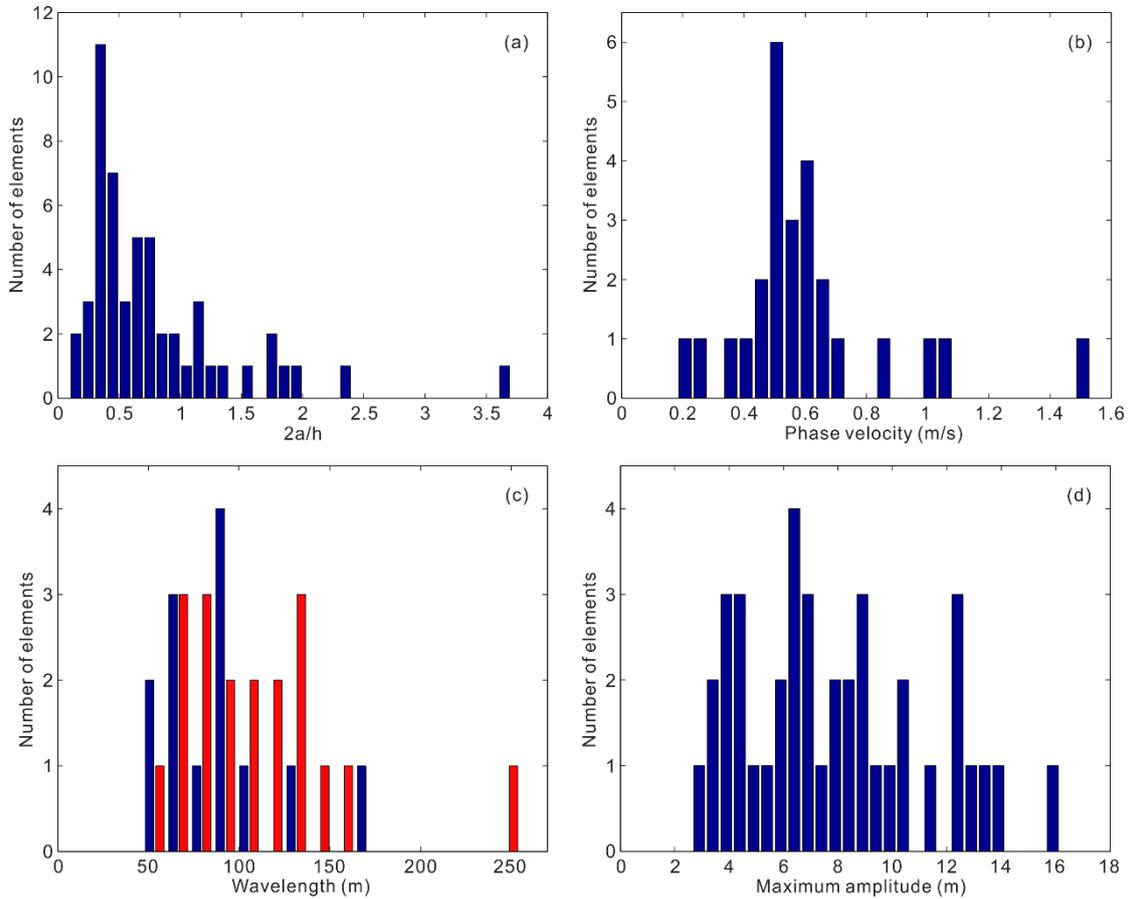

264 of the calculated value). The apparent phase velocities of the mode-2 ISWs in the study area are on the order of 0.5 m/s (Fig.
265 6b), and most of the mode-2 ISWs propagate in the shoreward direction. We have traced back the time when each ISWs in
266 the study area (mainly the ISWs located on the continental shelf) appeared at the continental shelf break using the ISWs
267 phase velocity of 0.5 m/s, as shown in Fig. 5c, in hours. Combined with Fig. 5a, it is found that from 2 December 2004 to 8
268 December 2004, the ISWs traced back to the continental shelf break appeared at around 12:00 and 00:00 (or 24:00) in a day,
269 and relatively more appeared around 12:00; From 10 December 2004 to 13 December 2004, most of the ISWs traced back to
270 the continental shelf break appeared at around 24:00 (or 0:00) in a day; From 14 December 2004 to 18 December 2004, the
271 ISWs traced back to the continental shelf break appeared at around 12:00 and 24:00 (or 0:00) in a day. The mode-2 ISWs
272 observed in the study area may be generated by the interaction between the internal tide and the continental shelf break.

284

285 **3.2 Phase Velocity and Wavelength Characteristics of the Mode-2 ISWs in Study Area**

286 Inspired by the work of Maderich et al. (2015) and Chen et al. (2014), we respectively calculated the relationships
 287 between the dimensionless phase velocity and the dimensionless amplitude, the dimensionless wavelength and the
 288 dimensionless amplitude, the phase velocity (apparent phase velocity) and the maximum amplitude, the wavelength
 289 (equivalent wavelength) and the maximum amplitude, the phase velocity (apparent phase velocity) and the pycnocline depth,
 290 the phase velocity (apparent phase velocity) and the pycnocline thickness. Figure 7 shows the relationship between the
 291 dimensionless phase velocity U_0/C and the dimensionless amplitude $2a/h_2$ of the observed 26 mode-2 ISWs (with relatively
 292 small errors) in the study area. When $2a/h_2 < 1$, the relationship between the dimensionless phase velocity and the
 293 dimensionless amplitude of the observed mode-2 ISWs in the study area has the trends respectively given by Kozlov and

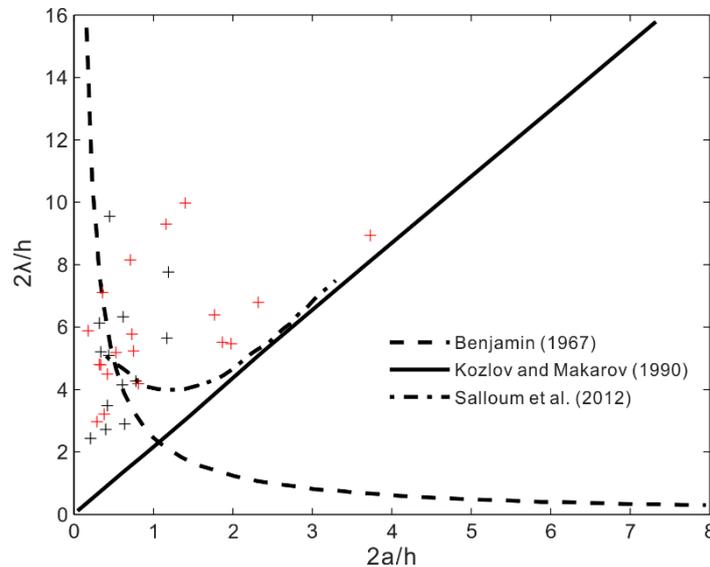

294 Makarov (1990), as well as Salloum et al. (2012). That is, the dimensionless phase velocity of the mode-2 ISWs increases
295 with the increasing dimensionless amplitude, but with different growth rates. When $2a/h_2 > 1$, the relationship between the
296 dimensionless phase velocity and the dimensionless amplitude of the observed mode-2 ISWs in the study area is closer to the
297 result predicted by the deep water weakly nonlinear theory (Benjamin, 1967). That is, The dimensionless phase velocity of
298 the mode-2 ISWs increases with the increasing dimensionless amplitude at a relatively small growth rate. Figure 8 shows the
299 relationship between the dimensionless wavelength $2\lambda/h_2$ and the dimensionless amplitude $2a/h_2$ of the observed 32 mode-2
300 ISWs (there are 13 ISWs on the survey lines in SW-NE direction, and 19 ISWs on the survey lines in NE-SW direction, see
301 Fig. 6c) in the study area, where the black and red crosses denote the ISWs on the survey lines in SW-NE direction and in
302 NE-SW direction, respectively. The survey line in SW-NE direction is consistent with the movement direction of the ISWs.
303 Use Eq. (1) to correct the apparent wavelength to obtain the actual wavelength. The survey line in NE-SW direction is
304 opposite to the movement direction of the ISWs. Use Eq. (2) to correct the apparent wavelength to obtain the actual
305 wavelength. Figure 8 shows the result after correcting the apparent wavelength of the ISWs. When using Eq. (1) and Eq. (2)
306 to correct the apparent wavelength, the phase velocity of the ISWs estimated in Fig. 7 needs to be used. The dimensionless
307 wavelengths of the ISWs with the large error in the estimation of the phase velocity are not shown in Fig. 8. Observing Fig. 8,
308 it can be found that when $2a/h_2 < 1$, the relationship between the dimensionless wavelength and the dimensionless amplitude
309 of the observed mode-2 ISWs in the study area is closer to the result predicted by the deep water weakly nonlinear theory
310 (Benjamin, 1967). That is, the dimensionless wavelength of the mode-2 ISWs decreases with the increasing dimensionless
311 amplitude. When $2a/h_2 > 2$, the relationship between the dimensionless wavelength and the dimensionless amplitude of the
312 observed mode-2 ISWs in the study area is closer to the solution of Salloum et al. (2012). That is, the dimensionless
313 wavelength of the mode-2 ISWs increases with the increasing dimensionless amplitude. When $1 < 2a/h_2 < 2$, the dimensionless
314 wavelength of the observed mode-2 ISWs in the study area is higher than that predicted by the deep water weakly nonlinear
315 theory (Benjamin, 1967) and Salloum et al. (2012).
316

317

318 **Figure 7.** The relationship between the dimensionless phase velocity and the dimensionless amplitude of the mode-2 ISWs observed
319 in the study area. The black crosses denote the seismic observation results of the mode-2 ISWs.

320

321

322 **Figure 8.** The relationship between the dimensionless wavelength and the dimensionless amplitude of the mode-2 ISWs observed in
323 the study area. The black and red crosses denote the ISWs on the survey lines in SW-NE direction and in NE-SW direction,
324 respectively.

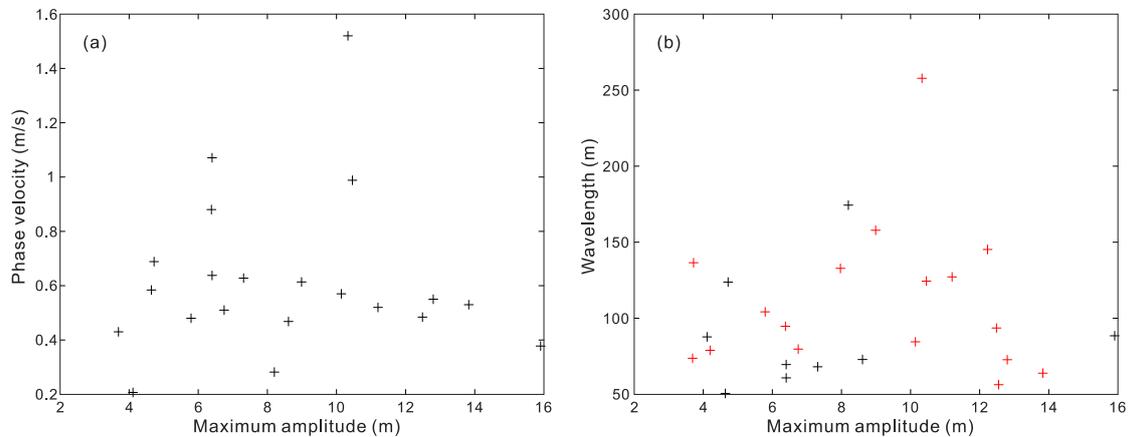

325

326 The relationship between the phase velocity and the maximum amplitude of the mode-2 ISWs observed in the study
327 area, and the relationship between the wavelength and the maximum amplitude are shown in Figs. 9a and 9b, respectively. It
328 can be found that the phase velocity and wavelength of the mode-2 ISWs in the study area are less affected by the maximum

329 amplitude. There is no obvious linear correlation between phase velocity and maximum amplitude, as well as between
330 wavelength and maximum amplitude (Figs. 9a and 9b). When the maximum amplitudes are between 6 m and 11 m, the
331 variety range of phase velocity is relatively large, and there is a significant increase in phase velocity (Fig. 9a). When the
332 maximum amplitudes are between 7 m and 13 m, there is a significant increase in wavelength (Fig. 9b). The relationships
333 between the phase velocity and the pycnocline depth, as well as the phase velocity and the pycnocline thickness of the
334 observed mode-2 ISWs in the study area are shown in Figs. 10a and 10b, respectively. As for the observed mode-2 ISWs in
335 the study area, their pycnocline depths are mainly concentrated in the range of 40-70 m, and their pycnocline thicknesses
336 (equivalent pycnocline thickness) are mainly concentrated in the range of 10-60 m. As with the numerical simulation results
337 of Chen et al. (2014), the phase velocity of the observed mode-2 ISWs in the study area has the trends to increase slowly
338 with the increasing pycnocline depth and pycnocline thickness, respectively. The trend mentioned above is not completely
339 monotonous in Fig. 10, which is manifested as the large variation range of the phase velocity on the vertical axis. We analyse
340 it is caused by the fact that other factors (such as seawater depth), other than the pycnocline depth and the pycnocline
341 thickness, also affect the phase velocity.

352

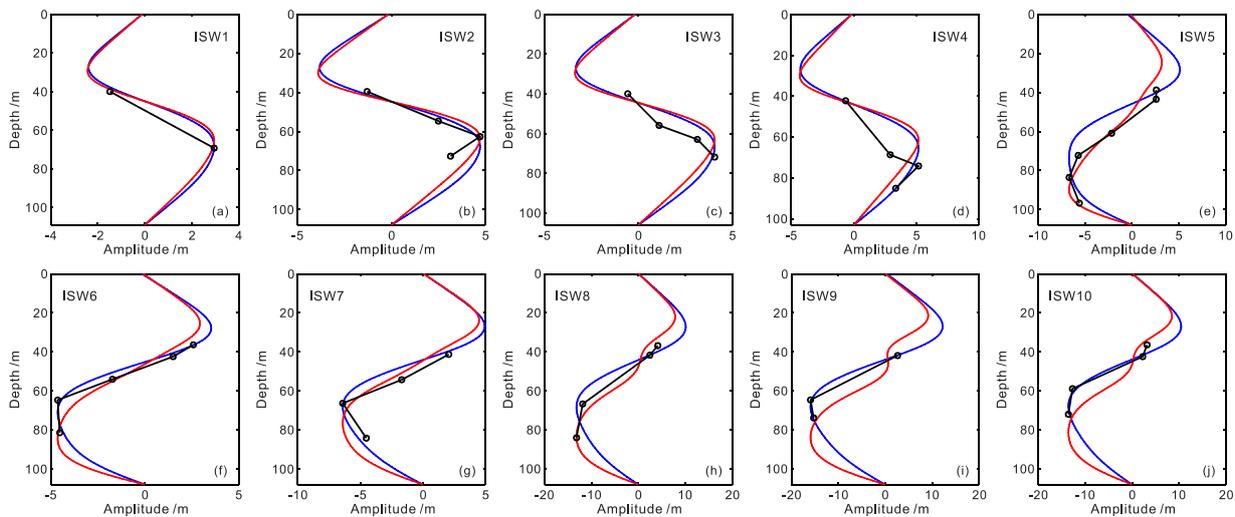

353 3.3 Vertical Structure Characteristics of the Mode-2 ISWs' Amplitude in Study Area

354 Observing the vertical structure of the mode-2 ISWs' amplitude in the study area, it is found that they follow the
355 following characteristics as a whole. The amplitude of ISWs in the upper half of the pycnocline decreases with the increasing
356 seawater depth. The amplitude of ISWs in the lower half of the pycnocline firstly increases and then decreases with the
357 increasing seawater depth (see Figs. 11 and 12 in this paper, Fig. 5 of Fan et al., 2021a, and Fig. 6 of Fan et al., 2021b). Due
358 to the influence of the pycnocline centre deviation on the development of the vertical structure of the ISWs' amplitude, the
359 vertical structure of the mode-2 ISWs' amplitude in the study area generally only exhibits part of the characteristics given by
360 the vertical mode function (the amplitude of the ISWs in the upper and lower half of the pycnocline firstly increases and then
361 decreases with the increasing seawater depth, respectively, as shown by the blue and red curves in Figs. 11 and 12). Since
362 the pycnocline centre of most of the mode-2 ISWs observed in the study area deviates upwards, the ISWs structure at the top
363 is not as well developed as the ISWs structure at the bottom. Therefore, the amplitude of ISWs in the upper half of the
364 pycnocline usually decreases with the increasing seawater depth. Figure 11 shows the vertical structure of the amplitude of
365 the 10 mode-2 ISWs ISW1-ISW10 in the survey line L84. The pycnocline centres corresponding to ISW1-ISW7 all deviate
366 upwards (see the degree to which the mid-depth of the pycnocline deviates from 1/2 seafloor depth in Table 1, the positive
367 sign indicates that the pycnocline deviates upward, and the negative sign indicates that the pycnocline deviates downward),
368 Among them, ISW1-ISW4 (Fig. 11a-d) and ISW7 (Fig. 11g) were only picked up one reflection event in upper half of the
369 pycnocline. From ISW6 (Fig. 11f), it can be seen that the amplitude of ISWs in the upper half of the pycnocline decreases
370 with the increasing seawater depth. From ISW2 (Fig. 11b), ISW4 (Fig. 11d), ISW5 (Fig. 11e), and ISW7 (Fig. 11g), it can be
371 clearly seen that the amplitude of ISWs in the lower half of the pycnocline firstly increases and then decreases with the

372 increasing seawater depth. The pycnocline centres corresponding to ISW8-ISW10 all slightly deviate downwards (see the
373 degree to which the mid-depth of the pycnocline deviates from 1/2 seafloor depth in Table 1, the positive sign indicates that
374 the pycnocline deviates upward, and the negative sign indicates that the pycnocline deviates downward). From ISW8 (Fig.
375 11h) and ISW10 (Fig. 11j), it can be seen that the amplitude of ISWs in the upper half of the pycnocline decreases with the
376 increasing seawater depth. Figure 12 shows the vertical structure of the amplitude of the four mode-2 ISWs (ISW11, ISW12,
377 ISW16, and ISW17) in the survey line L74. The pycnocline centres corresponding to ISW11, ISW12, ISW16, and ISW17
378 significantly deviate downwards (see the degree to which the mid-depth of the pycnocline deviates from 1/2 seafloor depth
379 in Table 2, the positive sign indicates that the pycnocline deviates upward, and the negative sign indicates that the
380 pycnocline deviates downward), which makes the ISWs structure at the top more developed. From ISW11, ISW12, and
381 ISW17 (Fig. 12a, b, d), it can be seen that the amplitude of the ISWs in the upper half of the pycnocline firstly increases and
382 then decreases with the increasing seawater depth.

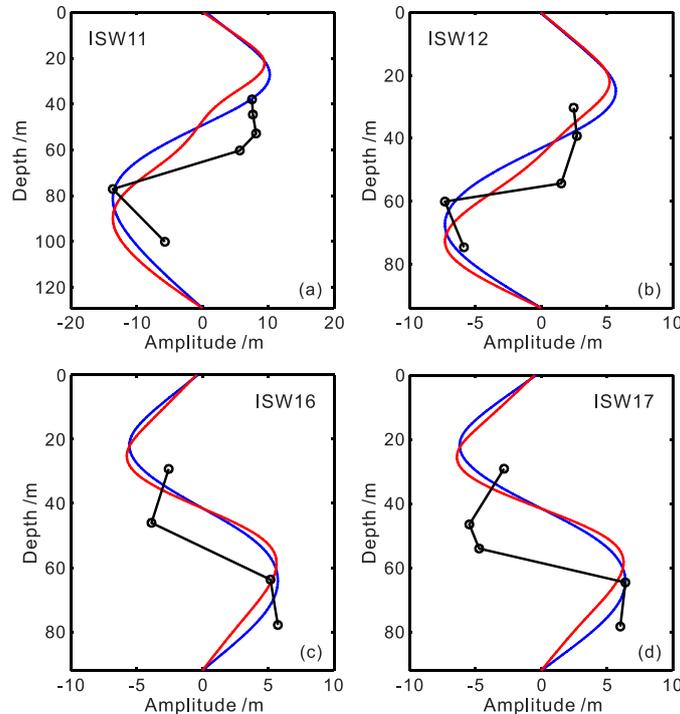

383

384

385 **Figure 11. (a)-(j) respectively demonstrate the vertical structure characteristics of the amplitude of the 10 mode-2 ISWs ISW1-**
386 **ISW10 in the survey line L84 as well as the vertical mode function fitting results. The black circles denote the observed ISWs'**
387 **amplitudes at different depths. The blue curves are the linear vertical mode function (nonlinear correction is not considered), and**
388 **the red curves are the first-order nonlinear vertical mode function (nonlinear correction is considered).**

389

390

391 **Figure 12. (a)-(d) respectively demonstrate the vertical structure characteristics of the amplitude of the four mode-2 ISWs (ISW11,**
392 **ISW12, ISW16, and ISW17) in the survey line L74 as well as the vertical mode function fitting results. The black circles denote the**
393 **observed ISWs' amplitudes at different depths. The blue curves are the linear vertical mode function (nonlinear correction is not**
394 **considered), and the red curves are the first-order nonlinear vertical mode function (nonlinear correction is considered).**

395

396 In order to study the vertical structure of the mode-2 ISWs' amplitude in more detailed for the study area, we
397 respectively compare the observation result with the linear vertical mode function (nonlinear correction is not considered, the
398 blue curves in Figs. 11 and 12) and the first-order nonlinear vertical mode function (considering nonlinear correction, the red
399 curves in Figs. 11 and 12). The linear vertical mode function can be obtained by solving the eigenvalue equation that
400 satisfies the Taylor-Goldstein problem (Holloway et al., 1999): $d^2\varphi(z)/dz^2 + [N^2(z) - \omega^2]/C^2\varphi(z) = 0$, $\varphi(0) = \varphi(-H) = 0$. Where $\varphi(z)$
401 represents the linear vertical mode function, C is the linear phase velocity, $N(z)$ is the Brunt-Väisälä frequency, and ω is the
402 wave frequency. The first-order nonlinear vertical mode function is obtained by adding a nonlinear correction term to the
403 linear vertical mode function (Lamb and Yan, 1996), and it can be expressed by $\varphi_m(z) = \varphi(z) + \eta_0 T(z)$. Where η_0 is the ISWs
404 maximum amplitude in the vertical direction, and $T(z)$ is the first-order nonlinear correction term. The detailed calculation
405 process is described in Gong et al. (2021). Observing Fig. 11, it can be found that the overall nonlinearity of the ISWs ISW5
406 (Fig. 11e) and ISW8 (Fig. 11h) on the survey line L84 is relatively strong, and the first-order nonlinear vertical mode
407 function considering nonlinear correction can be used to better fit the vertical structure of the amplitude (the red curves in
408 Fig. 11e, h). The nonlinearity is relatively strong at the bottom of ISW2 (the seawater depth range is 60-80 m in Fig. 11b),
409 the top of ISW7 (the seawater depth range is 40-60 m in Fig. 11g), and the top of ISW10 (the seawater depth is about 40 m

410 in Fig. 11j). And the first-order nonlinear vertical mode function considering nonlinear correction can be used to better fit the
411 vertical structure of the amplitude (the red curves in Fig. 11b, g, j). The overall nonlinearity of ISW1 (Fig. 11a), ISW3 (Fig.
412 11c), ISW6 (Fig. 11f), and ISW9 (Fig. 11i) is relatively weak, and the linear vertical mode function can be used to better fit
413 the vertical structure of the amplitude. The nonlinearity is relatively weak at the top of ISW2 (the seawater depth range is 40-
414 60 m in Fig. 11b), the bottom of ISW7 (the seawater depth range is 60-90 m in Fig. 11g), and the bottom of ISW10 (the
415 seawater depth is below 40 m in Fig. 11j). The linear vertical mode function can be used to better fit the vertical structure of
416 the amplitude (the blue curves in Fig. 11b, g, j). The above analysis reflects that the vertical structure of the mode-2 ISWs'
417 amplitude in the study area is affected by the nonlinearity degree of the ISWs. Observing Fig. 12, it can be found that neither
418 the linear vertical mode function (without considering nonlinear correction) nor the first-order nonlinear vertical mode
419 function (with consideration of nonlinear correction) can be used to well fit the vertical structure of the amplitude of the
420 ISWs ISW11, ISW12, ISW16, and ISW17 on L74 (especially the position of the upper half of the pycnocline). The ISWs
421 ISW11, ISW12, ISW16, and ISW17 on the survey line L74 have the large downward deviation of the pycnocline centre (see
422 the degree to which the mid-depth of the pycnocline deviates from 1/2 seafloor depth in Table 2, the positive sign indicates
423 that the pycnocline deviates upward, and the negative sign indicates that the pycnocline deviates downward). We observed
424 the fitting result of the vertical amplitude of the ISWs with the large downward pycnocline deviation on other lines of the
425 study area (not shown in this article), and found that the fitting result of the vertical amplitude is usually poorer than that of
426 the ISWs corresponding to the upward deviation of the pycnocline (especially the position of the upper half of the
427 pycnocline). We believe that when the pycnocline centre has the large downward deviation, the vertical mode function
428 (including the linear vertical mode function without considering nonlinear correction and the first-order nonlinear vertical
429 mode function considering nonlinear correction) cannot be used to well fit the vertical structure of the mode-2 ISWs'
430 amplitude in the study area. The above analysis once again reflects that the pycnocline deviation (especially the downward
431 deviation of the pycnocline) affects the vertical structure of the mode-2 ISWs' amplitude in the study area.

432 4 Discussion

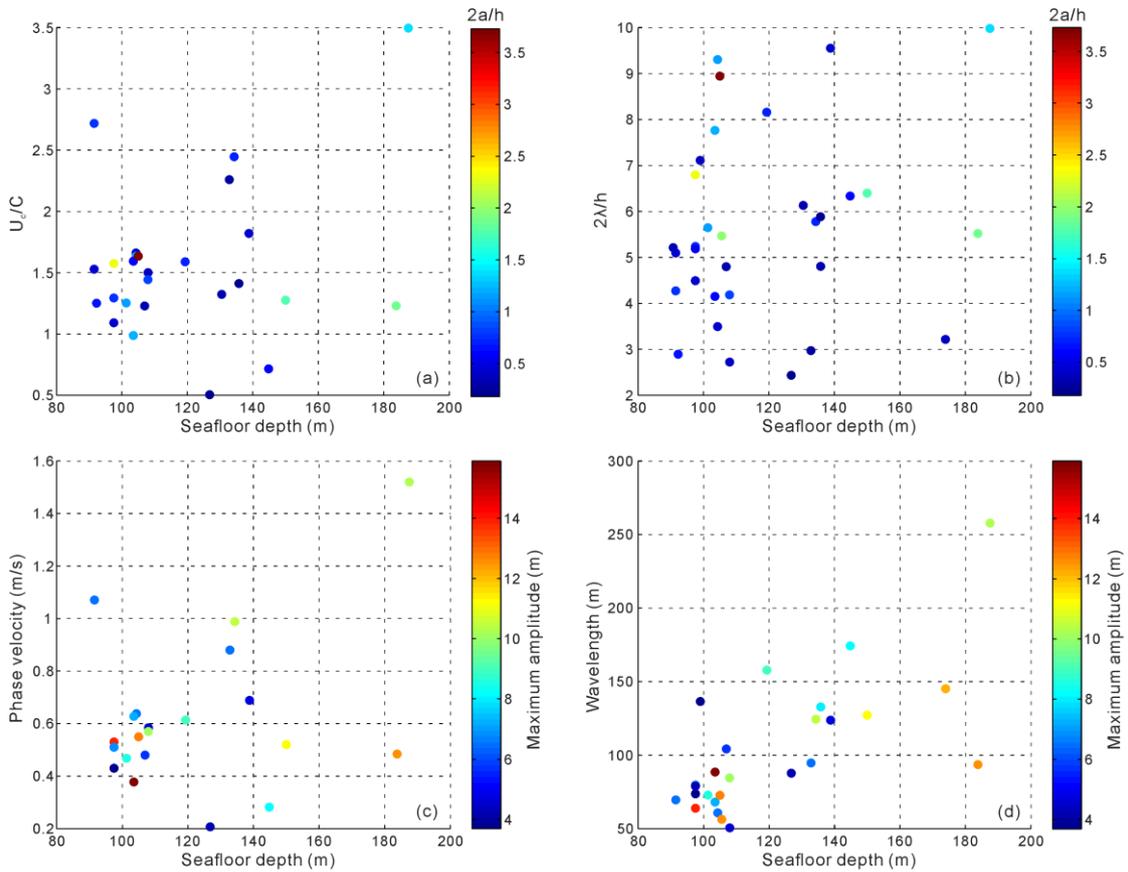

433 As for the relationship between the dimensionless phase velocity and the dimensionless amplitude of the mode-2 ISWs
434 in the study area, as well as the relationship between the dimensionless wavelength and the dimensionless amplitude, both of
435 them are not strictly monotonous in the case of smaller amplitude ($2a/h_2 < 1$) and show the characteristics of multi-parameter
436 controlling. For this reason, we analysed the influence of seawater depth on the dimensionless phase velocity and
437 dimensionless wavelength of the mode-2 ISWs in the study area. The results are shown in Fig. 13a and b, respectively.
438 Observing Fig. 13a, it can be found that in the shallow seawater (the seafloor depth is less than 120 m) the dimensionless
439 phase velocity variation range is small, and there are both the large-amplitude mode-2 ISWs ($2a/h_2 > 2$) and the small-
440 amplitude mode-2 ISWs ($2a/h_2 < 2$). In the deep seawater (or at the shelf break, the seafloor depth is greater than 120m), the
441 smaller-amplitude mode-2 ISWs ($2a/h_2 < 1$, dark blue filled circles in Fig. 13a) have a large dimensionless phase velocity

442 variation range. The maximum dimensionless phase velocity can reach 2.45, and the minimum can reach 0.5. In particular,
443 the smaller dimensionless phase velocities are mainly concentrated in the deep seawater, so that in Fig. 7 when $2a/h_2 < 1$ the
444 relationship between the dimensionless phase velocity and the dimensionless amplitude of the mode-2 ISWs has the trend
445 given by Kozlov and Makarov (1990). The sharp decrease in the dimensionless phase velocities of the mode-2 ISWs with
446 smaller amplitudes in the deep seawater may be caused by the collision of the ISWs with the seafloor topography (including
447 the step) at the shelf break. In addition, from Fig. 10a and b, it can be found that on the whole, the pycnocline depth and the
448 pycnocline thickness of the larger-amplitude mode-2 ISWs ($2a/h_2 > 1$) are respectively smaller than the pycnocline depth and
449 the pycnocline thickness of the smaller-amplitude mode-2 ISWs ($2a/h_2 < 1$). Therefore, the phase velocities of the larger-
450 amplitude mode-2 ISWs ($2a/h_2 > 1$) are generally smaller than the phase velocities of the smaller-amplitude mode-2 ISWs
451 ($2a/h_2 < 1$). In Fig. 7 when $2a/h_2 > 1$, this makes the relationship between the dimensionless phase velocity and the
452 dimensionless amplitude of the mode-2 ISWs is closer to the result predicted by the deep water weakly nonlinear theory
453 (Benjamin, 1967). The above-analysed influences of the seawater depth (seafloor topography), the pycnocline depth and the
454 pycnocline thickness on the mode-2 ISWs phase velocity of the study area have caused the diversity of the relationship
455 between dimensionless phase velocity and dimensionless amplitude. That is, when $2a/h_2 < 1$, the relationship between the
456 dimensionless phase velocity and the dimensionless amplitude of the observed mode-2 ISWs in the study area has the trends
457 respectively given by Kozlov and Makarov (1990), as well as Salloum et al. (2012). when $2a/h_2 > 1$, the relationship between
458 the dimensionless phase velocity and the dimensionless amplitude of the observed mode-2 ISWs in the study area is closer to
459 the result predicted by the deep water weakly nonlinear theory (Benjamin, 1967).

460 Observing Fig. 13b, it can be found that the mode-2 ISWs with the smaller amplitudes ($2a/h_2 < 1$, the dark blue filled
461 circles in Fig. 13b) have a relatively large variation range of the dimensionless wavelength in the deep seawater (the seafloor
462 depth is greater than 120m). The largest dimensionless wavelength can reach up to 9.55 (corresponding to ISW2 on the
463 survey line L84, whose pycnocline deviation is large and waveform is asymmetric), and the smallest dimensionless
464 wavelength can reach 2.44, so that the dimensionless wavelength of the vertical axis in Fig. 8 can be reduced to 2.44 when
465 $2a/h_2 < 1$. The sharp decrease in the dimensionless wavelengths of the mode-2 ISWs with the smaller amplitudes ($2a/h_2 < 1$) in
466 deep seawater may be caused by the collision of the ISWs with the seafloor topography at the shelf break. The sharp increase
467 in dimensionless wavelengths of the mode-2 ISWs with the smaller amplitudes in deep seawater may be related to the
468 waveform asymmetry caused by the pycnocline deviation.

469

470

471 **Figure 13. (a) the relationship between the dimensionless phase velocity and the seawater depth of the mode-2 ISWs observed in**
472 **the study area, the colour of the filled circle indicates the dimensionless amplitude. (b) The relationship between the dimensionless**
473 **wavelength and the seawater depth of the mode-2 ISWs observed in the study area, the colour of the filled circle indicates the**
474 **dimensionless amplitude. (c) The relationship between the phase velocity and the seawater depth of the mode-2 ISWs observed in**
475 **the study area, the colour of the filled circle indicates the maximum amplitude. (d) The relationship between the wavelength and**
476 **the seawater depth of the mode-2 ISWs observed in the study area, the colour of the filled circle indicates the maximum amplitude.**

477

478 Fig. 13c and d respectively show the relationship between the phase velocity and the seawater depth, and the
479 relationship between the wavelength and the seawater depth of the mode-2 ISWs in the study area. The colour of the filled
480 circles in the figures represents the maximum amplitude. Observing Fig. 13c, it can be found that the seawater depth in the
481 study area has the great influence on the phase velocity of the mode-2 ISWs. In the shallow seawater area (the seawater
482 depth is less than 120 m), the phase velocity variety range is small. In the deep seawater area (the seawater depth is larger
483 than 120 m) the phase velocity has the large variety range. The maximum phase velocity is 1.52 m/s and the minimum phase
484 velocity is 0.21 m/s. In Fig. 9a, when the maximum amplitude is between 6 m and 11 m, the phase velocity has the larger
485 variety range, and there is the significant increase in the phase velocity. The above phenomenon is controlled by the seawater
486 depth. That is, in the deep seawater area (seawater depth greater than 120 m), for the ISWs with the maximum amplitude of
487 6-11 m, the phase velocity varies widely, and the maximum phase velocity of 1.52 m/s appears (Fig. 13c). Observing Fig.

488 13d, it can be found that the seawater depth in the study area has the great influence on the wavelength of the mode-2 ISWs.
489 On the whole, the wavelength of the ISWs increases with the increasing seawater depth. For the ISWs with the maximum
490 amplitude of 7-13 m, a considerable part of them are distributed in the deep seawater area (the seawater depth is larger than
491 120 m), making their wavelengths increase significantly. As a result, when the maximum amplitude is between 7 m and 13
492 m in Fig. 9b, there is the significant increase in the wavelength.

493 5 Conclusions

494 A regional study of the mode-2 ISWs in the Pacific coast of Central America was carried out by using seismic reflection.
495 Through the analysis of the typical seismic sections L84 and L74, it is found that when the degree of downward pycnocline
496 deviation is large, the influence of pycnocline deviation on the stability of the mode-2 ISWs is more complicated than when
497 the pycnocline deviates upwards. There are mode-2 ISWs with the large degree of downward pycnocline deviation but with
498 the relatively symmetrical waveform.

499 The observed relationship between the dimensionless phase velocity U/C and the dimensionless amplitude $2a/h_2$ of the
500 mode-2 ISWs in the study area was analysed. When $2a/h_2 < 1$, U/C increases with the increasing $2a/h_2$, divided into two parts
501 with different growth rates. When $2a/h_2 > 1$, U/C increases with the increasing $2a/h_2$ at a relatively small growth rate. The
502 observed relationship between the dimensionless wavelength $2\lambda/h_2$ and the dimensionless amplitude $2a/h_2$ of the mode-2
503 ISWs in the study area was also analysed. When $2a/h_2 < 1$, $2\lambda/h_2$ decreases with the increasing $2a/h_2$. When $2a/h_2 > 2$, $2\lambda/h_2$
504 increases with the increasing $2a/h_2$. As for the relationships between U/C and $2a/h_2$, as well as $2\lambda/h_2$ and $2a/h_2$ of the mode-2
505 ISWs in the study area, both of them show the characteristics of multi-parameter controlling. The influences of the seawater
506 depth (seafloor topography), the pycnocline depth, and the pycnocline thickness on the mode-2 ISWs phase velocity of the
507 study area have caused the diversity of the relationship between U/C and $2a/h_2$.

508 The vertical structure of the mode-2 ISWs' amplitude in the study area is affected by the nonlinearity degree of the
509 ISWs. Part of the mode-2 ISWs with the strong nonlinearity (or the part with strong nonlinearity of the ISWs in the vertical
510 direction) can use the first-order nonlinear vertical mode function (nonlinear correction is considered) to better fit the vertical
511 structure of the amplitude. The pycnocline deviation (especially the downward deviation of the pycnocline) affects the
512 vertical structure of the mode-2 ISWs' amplitude in the study area. When the pycnocline centre has the large downward
513 deviation, the vertical mode function cannot be used to well fit the vertical structure of the mode-2 ISWs' amplitude in the
514 study area.

515 **Code and data availability.** The full seismic data are provided by MGDS (The Marine Geoscience Data System)
516 (<http://www.marine-geo.org/>), available for academic research at www.marine-geo.org/tools/search/entry.php?id=EW0412.
517 The temperature and salinity data comes from CMEMS (Copernicus Marine Environment Monitoring Service)
518 (<http://marine.copernicus.eu/services-portfolio/access-to-products/>).

519 **Author contribution.** The concept of this study was developed by Haibin Song and extended upon by all involved. Wenhao
520 Fan implemented the study and performed the analysis with guidance from Haibin Song, Yi Gong, Shun Yang and Kun
521 Zhang collaborated in discussing the results and composing the manuscript.

522 **Competing interests.** The authors declare that they have no conflict of interest.

523 **Acknowledgements.** We thank the captain, crew, and science party of R/V Maurice Ewing cruise EW0412 for acquiring the
524 seismic data. We appreciate MGDS and CMEMS for their supporting data used in this study. This work is supported by the
525 National Natural Science Foundation of China (Grant Number 41976048) and the National Key R&D Program of China
526 (2018YFC0310000).
