27 **Abstract**

28 In this paper, we have developed the Matlab code for a weighted hybrid of particle swarm
29 optimization (PSO) and gravitational search algorithm (GSA) known as wPSOGSA, GSA, and
30 PSO algorithms to interpret one-dimensional magnetotelluric (MT) data for some corrupted and
31 non-corrupted synthetic data, as well as two examples of MT field data over different geological
32 terrains: (i) geothermal rich area, Island of Milos, Greece, and (ii) Southern Scotland due to the
33 occurrence of a significantly high electrical conductivity anomaly under crust and upper mantle
34 extending from the Midland Valley across the Southern Uplands into northern England. Even
35 though the fact that many models provide a good fit in a large predefined search space, specific
36 models do not fit well. As a result, we used a Bayesian statistical technique to construct and assess
37 the posterior probability density function (PDF) rather than picking the global model based on the
38 lowest misfit error. This is proceeded by 68.27 % confidence interval for selecting a region where
39 PDF is more prevalent to estimate the mean model which is more accurate and close to the true
40 model. For illustration, correlation matrices show a significant relationship among layer
41 parameters. The findings indicate, the wPSOGSA is less sensitive to model parameters and
42 produces well, more stable and reliable results with the least uncertainty in the model that is
43 compatible with existing borehole samples. Furthermore, the present methods resolve two
44 additional geologically significant layers, one highly conductive (less than $1.0 \Omega\text{m}$) and another
45 resistive ($300.0 \Omega\text{m}$) over the Island of Milos, Greece, characterized by alluvium and volcanic
46 deposits, respectively, as corroborated by borehole stratigraphy.

50

51

52

53 **1.0 Introduction**

54 The magnetotelluric (MT) method is a natural source electromagnetic method that explores
55 various natural resources, namely hydrocarbon, minerals, geothermal prospects, groundwater,
56 metalliferous ores, etc. (Nabighian and Asten, 2002; Simpson and Bahr, 2005). Due to its
57 instability, non-unique solution, and algorithm sensitivity, the MT data interpretation is thought-
58 provoking. Many researchers have attempted and developed various inversion algorithms to
59 interpret, improve the model accuracy, convergence speed, stability and reduce the uncertainty of
60 the solutions (Kirkpatrick, et al., 1983; Constable et al., 1987; Rodi and Mackie, 2001; Li et al.,
61 2018; Zhang et al., 2019; Khishe and Mosavi, 2020). There are mainly two categories of the
62 inversion algorithm: first, the local optimization methods namely Conjugate gradient, Levenberg-
63 Marquardt/Ridge regression, Newton-Gauss, Steepest descent, and Occam inversion, requires
64 good initial guess (Shaw and Srivastava, 2007; Wen et al., 2019; Roy and Kumar, 2021) and
65 another is global optimization techniques (i.e., Ant colony optimization, Genetic algorithm,
66 Particle swarm optimization, Gravitational search algorithm, Simulated annealing, etc.) does not
67 require initial guess. Many researchers have carried out numerous metaheuristic optimization
68 algorithms to invert MT data (Dosso and Oldenburg, 1991; Pérez-Flores and Schultz, 2002;
69 Miecznik et al., 2003; Sen and Stoffa, 2013). These algorithms are inspired by the natural
70 phenomenon and have various geophysical application include Particle Swarm Optimization
71 (Kennedy and Eberhart, 1995; Essa et al., 2023), Genetic Algorithm (Whitley, 1994), Bat
72 algorithm (Yang, 2010a; Essa and Diab, 2023), Differential Evolution (Storn and Price, 1997),
73 biogeographically based Optimization (Simon, 2008), Firefly algorithm (Yang, 2010b), Grey
74 Wolves Optimizer (Mirjalili et al., 2014), Ant Colony (Colormi et al., 1991), Gravitational Search
75 Algorithm (Rashedi et al., 2009) and novel barnacles mating optimization algorithm (Ai et al.,
76 2022).

77 However, unique characteristics, namely exploration and exploitation, persist in any global
78 optimization algorithms. For example, the PSO algorithm has a very high potential for

79 exploitation, which implies that the algorithm performs well in local search but is inferior in
80 exploration (Şenel et al., 2019). This suggests that the algorithm has a limited capacity to estimate
81 the best model in an extensive search range. Because of low exploration characteristics, it gets
82 trapped at the local minima (Mirjalili and Hashim, 2010). So, integrating the two algorithms with
83 opposite characteristics is the best way to balance exploration and exploitation characteristics to
84 achieve better solutions than the results obtained from an individual algorithm.

85 Here, we utilized wPSOGSA, a new global optimization method that takes into account the
86 algorithm based on natural behavior seen in birds, fish, and insects known as Particle swarm
87 optimization (PSO) and gravity-based Newton's law (with high exploration capability) known as
88 Gravity search algorithm (GSA). Researchers interested in artificial intelligence and developing
89 effective optimization algorithms for comparative analysis of different metaheuristic algorithms
90 (Pace et al., 2022) have been drawn to notable characteristics in such social behavior. The
91 wPSOGSA, PSO, and GSA are used to estimate resistivity distribution of 1D multi-layered earth
92 model using synthetic (noise free and noisy) data for three and four layers cases taken from (Shaw
93 and Srivastava, 2007)) and Xiong et al. (2018), respectively and field MT sounding data for six
94 and four layers cases taken from (Hutton et al., 1989) and (Jones and Hutton, 1979) respectively.F

95 Furthermore, numerous (here 10000) models that fit well are optimized for getting the
96 mean model, which is proceeded by calculating posterior PDF based on Bayesian concepts
97 using all accepted models to find the optimal mean solution with the least uncertainty, as well
98 as a correlation matrix to determine the relationships among the layer parameters. Thus, the
99 research reveals that the wPSOGSA method may be utilized to provide a more accurate and
100 reliable model with superior stability, a quick rate of convergence, and the least amount of
101 model uncertainty.

102

103

104

105 **2.0 Data and Methodology**

106 **2.1 Synthetic and field data**

107 Different MT datasets are utilized to evaluate the proposed wPSOGSA algorithm's effectiveness,
108 sensitivity, stability, and robustness in outlining the genuine subsurface structure. These datasets
109 are noise-free and Gaussian noise synthetic data produced for several geological formations, and
110 two MT field data have been optimized for analysis.

111 To demonstrate and evaluate the robustness of the present algorithms, we have generated
112 a synthetic MT apparent resistivity and apparent phase data without noise and with noise levels
113 (10 % and 20 % noise) considering a three-layer typical continental crustal model with a total
114 thickness of 33000 m (i.e., 33.0 km) having a resistivity of upper-crust 30000.0 Ωm with 15000
115 m (i.e., 15 km) thickness (high resistive layer) and resistivity of middle crust 5000.0 Ωm with
116 18000 m (i.e., 18.0 km) thickness (reasonable low resistive layer) underlain by 1000 Ωm (low
117 resistive) half space taken from (Shaw and Srivastava, 2007).

118 For the second example of the synthetic data, a typical four-layer HK-type of earth model
119 taken from Xiong et al. (2018) is generated by forward modeling equations for the demonstration
120 of the wPSOGSA, PSO, and GSA algorithms and compared their performance with Improved
121 Differential Evolution (IDE) results obtained by Xiong et al. (2018).

122 We utilized the first example of field data taken from (Hutton et al., 1989), the Island of
123 Milos, Greece. Milos is a part of the South Aegean Active Volcanic Arc, an example of an
124 emergent volcanic edifice (Stewart and McPhie, 2006) formed by monogenetic effusive and
125 explosive magmatism pulses. Milos is the world's biggest exporter of bentonite, and it also has a
126 diverse variety of metalliferous and non-metalliferous mineral reserves. It's a conserved on-land
127 laboratory for studying shallow underwater hydrothermal ore-forming processes. The
128 accompanying shallow subsurface hydrothermal venting fields have developed significantly less
129 attention. In ("Dawes, 1986), used magnetotelluric data to assess the resistivity structure of the
130 geothermal area on Milos west side. With around 3.0 km spacing, 37 MT probes in the bandwidth

131 of 100-0.01 Hz and 12 investigations in the bandwidth of 0.01-0.0001 Hz were installed along
132 with various profiles that were perpendicular to the Zephyria graben in the W-E direction, as well
133 as along the graben in S-N direction (Hutton et al., 1989).

134 Another field example of MT data from (Jones and Hutton, 1979) was picked to illustrate
135 our technique from Newcastleton (2.796° W, 55.196° N in Geographic coordinates), Southern
136 Uplands of Scotland. By the Southern Uplands fault, the Southern Uplands are isolated from the
137 Midland Valley. The bulk of the Southern Uplands comprises Silurian/Lower Paleozoic
138 sedimentary deposits such as greywackes and shales that originated in the Iapetus Ocean during
139 the late Neoproterozoic and early Paleozoic geologic eras. These rocks emerged from the seafloor
140 as an accretionary wedge during the Caledonian orogeny. The majority of the rocks are coarse
141 greywacke, a kind of sandstone that has been poorly metamorphosed and contains angular quartz,
142 feldspar, and small rock fragments. The Midland Valley and Northern England, on the other hand,
143 are known for their thick Carboniferous layers, which are used to measure coal.

144

145 **2.2 Forward Modelling- Magnetotelluric formulation for 1-D earth**

146 The ability to formulate an effective inversion method requires a thorough understanding of the
147 forward modeling technique for the issue of interest. Factors like frequency range, actual
148 resistivity, and layer thickness are used to create synthetic MT apparent resistivity, $\rho_a(\omega)$ and
149 apparent phase, $\varphi_a(\omega)$ data sets. The electromagnetic impedance (Z) for layered structures is
150 described in terms of an orthogonal electric field, magnetic field, wavenumber (k), reflection
151 coefficient (R), and exponent factor (τ_f) with angular frequency (ω) as (Ward and Hohmann,
152 1988):

$$153 \quad Z = \frac{\mu_0 \omega}{k} = \frac{E_x}{H_y} = -\frac{E_y}{H_x} \quad (1)$$

154 where, the wavenumber(k) = $\sqrt{-i\mu_0\omega/\rho}$, component of electric field (E_x and E_y) and magnetic
155 field component (H_x and H_y).

156 If displacement currents are not taken into account, Eq. (1) becomes

$$157 \quad Z = \frac{\mu_0 \omega}{\sqrt{-i\mu_0 \omega / \rho}} = \sqrt{i\mu_0 \omega \rho} = \sqrt{\mu_0 \omega \rho} e^{\frac{i\pi}{4}} = \omega \frac{(1 - R \tau_f)}{(1 + R \tau_f)} \quad (2)$$

158 Noisy impedance is calculated by the following equation

$$159 \quad Z_{noisy} = Z + Z \times (2 \times rand - 1) \times noise_{percent} \quad (3)$$

160 If the angle between impedance phase with E_x is 45° , then the resistivity (ρ) in half-space of
161 impedance $Z(\omega)$ and time period (T) can be written as

$$162 \quad \rho(\omega) = \frac{1}{\mu_0 \omega} |Z(\omega)|^2 = \frac{0.2T}{\mu_0} \left| \frac{E_x}{H_y} \right|^2 \quad (4)$$

163 Thus, the apparent resistivity and apparent phase are defined (Cagniard, 1953; Ward and
164 Hohmann, 1988) as follows:

$$165 \quad \text{Apparent resistivity, } \rho_a(\omega) = \frac{1}{\mu_0 \omega} [Z(\omega)Z^*(\omega)] \quad (5)$$

$$166 \quad \text{Apparent phase, } \varphi_a(\omega) = \tan^{-1} \left(\frac{\text{img}(Z(\omega))}{\text{real}(Z(\omega))} \right) \quad (6)$$

167 where, the exponent factor, $\tau_f = \exp(-2\gamma h)$, the induction parameter $\gamma = \sqrt{i\omega\mu_0/\rho}$, h is the
168 layer thickness, μ_0 is the magnetic permeability for free space, Z^* is the complex conjugate of
169 impedance, and the *rand* is used for generating random number between 0 and +1.

170

171 **2.3 Global optimization technique**

172 The techniques that we have used for joint modeling of metaheuristic global optimization namely
173 PSO, GSA, and wPSOGSA in Step-1 and posterior Bayesian probability density function
174 technique in Step-2 to obtain the global model by utilizing the synthetic data generated by using
175 forward modelling and field MT apparent resistivity and phase curves is depicted in the schematic
176 diagram (Fig. 1).

177

178 **Figure 1** Schematic diagram demonstrating the essential processes considered for joint modeling
 179 of metaheuristic global optimization (Step-1) and posterior PDF technique (Step-2) for obtaining
 180 the global model by utilizing the synthetic and field MT data.

181

182 2.4 Optimization and Error Estimation

183 In the present study, we have implemented a new innovative global optimization technique known
 184 as wPSOGSA, in which swarm particles and mass particles provide the best particle, i.e., the best
 185 model. The best model is chosen based on the fitness of the particles, and the cost function or
 186 objective function is used to estimate this fitness. Thus magnetotelluric (MT) inverse problem can
 187 be formulated through the forward modelling operator, $f(\mathbf{x})$, aim at achieving the resistivity
 188 model, which illuminates the observed data ρ and φ in the foremost. This operator combines the
 189 problem of physics and inverts the observed apparent resistivity and phase data to the resistivity-
 190 depth model, \mathbf{x} , as:

$$191 \quad (\rho, \varphi) = f(\mathbf{x}) \quad (7)$$

192 The cost function (fitness of the particle) is a mathematical relation between observed and
 193 calculated data and it is defined as the root mean square error (RMS):

$$RMS = \sqrt{\left\{ \frac{(\rho - \rho_C)^2}{N} + \frac{(\varphi - \varphi_C)^2}{N} \right\}} \quad (8)$$

Where N is the total observed data points, ρ and φ are the observed apparent resistivity and phase, ρ_C and φ_C are the computed apparent resistivity and phase data.

2.5 Particle swarm optimization

The particle swarm optimization (PSO) technique is a widespread evolutionary optimization approach for determining the optimal global solution to a nonlinear inverse problem (Kennedy and Eberhart, 1995). This technique is analogous to the particle's natural behavior in search of food with the help of collaborative support from the population represented by geophysical resistivity solutions/models (known as particles) in a swarming group. The best model/position obtained among the particles so far is stored for each iteration, which helps in search for the global best solution, defined by the fitness of each particle estimated using Eq. (8). The particles' velocity and location in the search space are defined for k^{th} particle at t^{th} iteration is given below:

$$v_k(t + 1) = wv_k(t) + c_1 \times rand \times (x_p - x_k(t)) + c_2 \times rand \times (x_g - x_k(t)) \quad (9)$$

$$x_k(t + 1) = x_k(t) + v_k(t + 1) \quad (10)$$

where w is the inertia weight set in between 0 and 1, c_1 and c_2 are a personal learning coefficient and a global learning coefficient, respectively, $v_k(t)$ is the velocity of the k^{th} particle at t^{th} iteration, and $rand$ is used for a random number between 0 and 1, x_p is the present best solution. x_g is the global best solution, $x_k(t)$ is the position of the k^{th} particle at t^{th} iteration. Particles change their position at each iteration to approach an optimum solution. The first, second, and third terms in Eq. (9) represent exploratory ability, private thought, and particle collaboration, respectively.

2.6 Gravitational search algorithm

The gravitational search algorithm (GSA) is a meta-heuristic algorithm based on Newton's gravitational law (Rashedi et al., 2009), which states that mass particles attract each other with a

219 gravitational force that is directly proportional to the product of their masses and inversely
 220 proportional to the square of the distance between them. It signifies that massive particles (here,
 221 particle represents the resistivity layer model/solution) attract to the neighboring lighter particles.
 222 Similar to PSO, the Gravitational search optimizer works with a population of particles known as
 223 mass particles in the universe. Thus the best model/solution/particle is achieved among the mass
 224 particles. The best model is defined by each particle's capability (i.e., the fitness) calculated using
 225 Eq. (8). The initialization of their position in the search spaces is given by:

$$226 \quad x = rand(N, D) \times (up - down) + down \quad (11)$$

227 where N, D are the number of particles/models, the dimension of the model; and up , and $down$
 228 are the upper and lower limit of the search range, respectively.

229 During execution time, the gravitational acting force on agent k^{th} from agent j^{th} at a specific
 230 time (t) is defined as:

$$231 \quad F_{k,j}(t) = G(t) \frac{M_{p,k}(t) * M_{a,j}(t)}{R_{k,j}(t) + \epsilon} (x_j(t) - x_k(t)) \quad (12)$$

232 where, $M_{a,j}$, and $M_{p,k}$ are the active and passive gravitational masses for particle j and k ,
 233 respectively, $x_j(t)$ is the position of the particle j at a time t for various parameters, $R_{k,j}(t)$ is
 234 Euclidian distance between two particles, and ϵ is a small constant.

235 Here, gravitational constant $G(t)$ at a specific time t is defined as (Kunche et al., 2015)
 236 and acceleration of k^{th} agent at t^{th} iteration for models is $ac_k(t)$ is defined as:

$$237 \quad ac_k(t) = \frac{F_k(t)}{M_k(t)} \quad (13)$$

238 Where, $F_{k,j}(t)$ the gravitational acting force on agent k from agent j and $M_k(t)$ is the mass of the
 239 object at a specific time (t).

$$240 \quad G(t) = G_0 \times \exp\left(-\alpha \times \frac{iter}{maxiter}\right) \quad (14)$$

241 where α , G_0 , $iter$, and $maxiter$ are descending coefficients, starting value of gravitational constant,
 242 current iteration, and maximum iterations, respectively.

243 The following equations are used to update the particle's velocity and location:

$$244 \quad v_k(t + 1) = rand \times v_k(t) + ac_k(t) \quad (15)$$

$$245 \quad x_k(t + 1) = x_k(t) + v_k(t + 1) \quad (16)$$

246 All the particles are randomly placed in the search range using Eq. (11) and then initializes the
247 particle's velocity. Meanwhile, the gravitational constant, total forces and acceleration are
248 computed, and the locations are updated. The end criteria is the misfit error (i.e. 10^{-9}) is taken in
249 our study.

250

251 **2.7 Weighted hybrid PSO-GSA (wPSOGSA)**

252 The weighted hybrid of PSO and GSA algorithm known as the wPSOGSA algorithm integrates
253 two essential characteristics, exploration (i.e., the ability of an algorithm to search the whole range
254 of a given parameter) and exploitation (i.e., the ability to converge the solution nearest to the best
255 solution) of the global optimization algorithm that increases its efficiency and converges the
256 objective function to achieve global minima. The velocity and location of the particles updated in
257 the wPSOGSA algorithm are illustrated in the schematic diagram (see Fig. 2).

258 The wPSOGSA combines the characteristic of social thinking of PSO and the searching
259 capability of GSA; thus, the particle's velocity is defined as

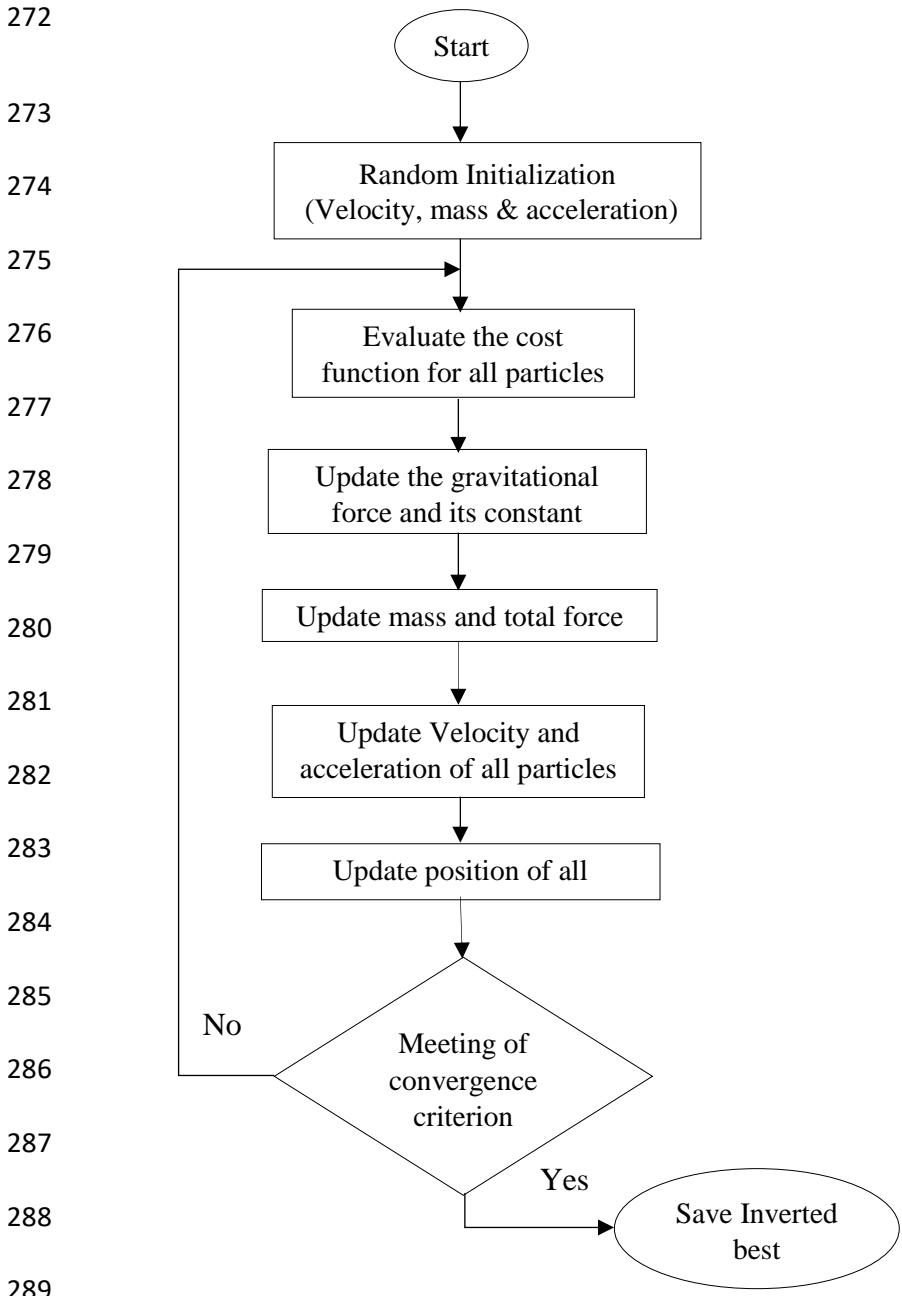

$$260 \quad v_k(t + 1) = w \times v_k(t) + c_1 \times rand \times ac_k(t) + c_2 \times rand \times (x_g - x_k(t)) \quad (17)$$

261 Where $v_k(t)$ is the velocity of the particle k at iteration t , w is the weight function (i.e., the constant
262 which helps to control the momentum of the algorithm to perform optimization properly), $ac_k(t)$
263 is the acceleration of agent k , x_g is the best solution, and the $rand$ is a random number lies between
264 0 and 1. At each iteration, particles updated their location to achieve the best solution defined as

$$265 \quad x_k(t + 1) = x_k(t) + v_k(t + 1) \quad (18)$$

266 The algorithm starts by randomly initializing the velocity, mass, and acceleration of the
267 particles. The cost function is evaluated for all particles for specified iterations to get the most

268 optimal solution, and inverted results are updated at each iteration. Equation (12), (17), and (18)
269 are used to update the gravitational force, velocity, and location of particles after initialization.
270 However, the velocity and position stop updating their values when the algorithm converge and
271 reaches the least error of the cost function.

290 **Figure 2** Flow chart of the weighted hybrid Particle Swarm Optimization and Gravity Search
291 Algorithm known as the wPSOGSA algorithm (after (Mirjalili and Hashim, 2010)).

292

293 **2.8 Bayesian probability density function**

294 In a Bayesian framework, the probability distribution of the model parameters (known as posterior
 295 probability distribution) is computed using given observed data and models obtained from
 296 inversion. The posterior for a model is calculated using Bayes' theorem and previous model space
 297 information. Individual model parameter ranges are incorporated in the prior knowledge. The two
 298 fundamental stages in the Bayesian statistics method are the representation of previous knowledge
 299 as a probability density function and calculating the likelihood functional derived from data misfit
 300 (Tarantola and Valette, 1982). Specific characteristics, such as the best fitting model, mean model,
 301 and correlation matrix may be determined from posterior distribution of models. According to the
 302 Bayes' theorem,

$$303 \quad \text{Posterior} = \text{prior} \times \text{likelihood} \quad (19)$$

304 As a result, our priori distribution function ($f(\mu)$) for the parameter, x_u , mean priori information,
 305 M , and t^2 is the mean uncertainty is defined as

$$306 \quad f(\mu) = \frac{1}{\sqrt{2\pi t^2}} \exp \left\{ -\frac{(x_u - M)^2}{2t^2} \right\} \quad (20)$$

307 and likelihood function is

$$308 \quad f(X|\mu) = \prod_{u=1}^n \frac{1}{\sqrt{2\pi\sigma^2}} \exp \left\{ -\frac{(x_u - \mu)^2}{2\sigma^2} \right\} \quad (21)$$

309 Hence the posterior density function calculated for a parameter (x_u) using mean (μ) and variance
 310 (σ^2) defined (Lynch, 2007) as

$$311 \quad f(\mu|X) = \frac{1}{\sqrt{t^2\sigma^2}} \exp \left\{ \frac{-(\mu - M)^2}{2t^2} + \frac{\sum_{u=1}^n (x_u - \mu)^2}{2\sigma^2} \right\} \quad (22)$$

312 The posterior Bayesian PDF is calculated from accepted models within a set of parameters, as
 313 shown below:

$$314 \quad P(X|E) = \frac{P(X)L(E|X)}{\sum_X P(X)L(E|X)} \quad (23)$$

315 where, $P(X|E)$ is the posterior probability distribution of the parameter (X) given the evidence
 316 (E), $P(X)$ is the prior information of (X) and $L(E|X)$ is the likelihood function of X .

317 After the application of PDF, the study is further proceeded by choosing Confidence
 318 Interval (CI) of 68.27 % that is based on the empirical rule, known as the 68-95-99.7 rule (Ross,
 319 2009). The model parameters below 68.27 % CI are discarded, and the remaining parameters are
 320 used for determining the mean model and uncertainty. Thus, the mean model (P_j) is calculated
 321 using the best models having PDF within a 68.27 % CI, defined in the following equation:

$$322 \quad P_j = \exp \frac{1}{Nd} \sum \ln(P_{j,k}) \quad (24)$$

323 Here accepted models are used to calculate the correlation matrix (i.e., correlation among
 324 model parameters lie between -1 and 1) using the following equation (Tarantola, 2005):

$$325 \quad CovP(l, j) = \frac{1}{Nd} \sum (P_{l,k} - P_l) (P_{j,k} - P_j) \quad (25)$$

$$326 \quad \text{and} \quad CorP(l, j) = \frac{CovP(l, j)}{\sqrt{CovP(l, l) \times CovP(j, j)}} \quad (26)$$

327 Here, N is the total number of models, d is used for the number of the layer parameters, $P_{j,k}$ is the
 328 j^{th} model parameter of k^{th} model where l and j both vary from 1 to d (number of layer parameters).
 329 $CovP(l, j)$ is the covariance matrix between model parameter l and j , $P_{l,k}$ is the model parameter
 330 l^{th} model parameter of k^{th} model and $CorP(l, j)$ is the correlation matrix between model parameter
 331 l and j .

332

333 **3.0 Results and analysis**

334 The effectiveness, sensitivity, stability, and robustness of the proposed wPSOGSA algorithm in
 335 identifying the authentic subsurface structure are evaluated using various MT datasets. These
 336 datasets consist of synthetic data with no noise and Gaussian noise, which simulate different
 337 geological formations. Additionally, two MT field datasets have been optimized for analysis.

338

339

340

341 **3.1 Application to synthetic MT data-Three layers case**

342 This synthetic MT data that was executed for 10000 runs keeping the same lower and upper bounds
 343 as given in Table 1, and iteration to 1000. Figure 3 shows (a) the observed apparent resistivity
 344 with the computed data, (b) the observed apparent phase with the computed data, (c) 1D inverted
 345 model by wPSOGSA (red color), GSA (green color) and PSO (blue color) with a true model (black
 346 color), and 2(d) shows the relation between misfit and iterations for the noise-free synthetic data.

347
 348 **Figure 3** The inverted MT response by PSO (blue color), GSA (green color), and hybrid
 349 wPSOGSA (red color) with a true model (black color) over three-layer synthetic data as shown in
 350 (a) observed and calculated apparent resistivity curve, (b) observed and calculated apparent phase
 351 curve, (c) 1D depth inverted model, and (d) misfit error versus iterations.

352 The misfit curve as shown in Fig. 3(d) is gradually decreasing with increasing iterations
 353 and becomes constant, where the algorithm converges. The PSO, GSA, and wPSOGSA converge
 354 at iterations 492, 35, and 316 with associated errors 1.51e-6, 3.97e-6, and 1.035e-8, and the
 355 associated computational time is 27.06 seconds, 1.75 seconds, and 3.35 seconds, respectively.
 356 Thus, the curves describes that wPSOGSA converges at the least RMS error. Whereas PSO, GSA,

357 and wPSOGSA using 10 % noisy synthetic data converge at 102, 88, and 358 iterations with an
 358 associated error are 0.00435, 0.00439, and 0.00426, and associated computational times are 5.61
 359 seconds, 4.40 seconds, and 3.80 seconds, respectively.

360 The 20 % noisy synthetic MT data that was executed for 10000 runs keeping the same
 361 lower bound, upper bound, and iteration. The well fitted inverted MT response (see Fig. 4) as
 362 follows: (a) the corrupted synthetic and calculated apparent resistivity data, (b) the corrupted
 363 synthetic and calculated apparent phase data, (c) the inverted 1D depth model, and (d) convergence
 364 response in terms of misfit error versus iterations. We analyzed Fig. 4(d) and found that the PSO,
 365 GSA, and wPSOGSA using noisy synthetic data converge at iterations 236, 7, and 73 with
 366 associated errors 0.0394, 0.0408, and 0.0393, respectively.

367
 368 **Figure 4** The inverted MT response by PSO (blue color), GSA (green color), and hybrid
 369 wPSOGSA (red color) with a true model (black color) over three-layer synthetic data with 20 %
 370 random noise as shown in (a) observed and calculated apparent resistivity curve, (b) observed and
 371 calculated apparent phase curve, (c) 1D depth inverted model, and (d) misfit error versus iterations.

372 **3.1.1 Bayesian analysis and uncertainty in model parameters**

373 Two methods are used to estimate mean solution and uncertainty: one method is the mean solution
 374 for all accepted best-fitted solutions acquired from 10,000 runs for all three global optimization
 375 techniques; another method is the model derived from all approved solutions using posterior
 376 Bayesian PDF within one standard deviation. To get the global best solutions in our study, we
 377 incorporated posterior PDF based on the Bayesian approach to enhance the efficacy of the inverted
 378 model and minimize the uncertainty in the model. The process for obtaining the mean solution is
 379 proceeded by selecting an initial threshold error which is essential because smaller the threshold
 380 value, more significant number of models with lesser uncertainty in the model parameters
 381 (Sharma, 2012). Thus, a more considerable threshold gives a lesser number of models with
 382 enormous uncertainty in the model parameter (Sen and Stoffa, 1996; Sharma, 2012). This is further
 383 proceeded by calculating the PDF for each parameter value using Eq. (22). In order to select values
 384 of each parameter that having higher posterior PDF, a 68.27 % CI is used. The mean model
 385 obtained from selected model parameters is near to the actual model.

386
 387 **Figure 5** Posterior Bayesian probability density function (PDF) with 68.27 % CI for wPSOGSA
 388 for three-layered synthetic data.

389 Figure 5 shows the output of posterior Bayesian PDF, which select model parameters
 390 with lesser error. The straight lines (dashed lines) present the actual value of the respective layer

391 parameters. The first layer thickness, second layer thickness, and first layer resistivity have
 392 higher uncertainties, i.e., 61.25 m, 51.47 m, and 210.61 Ωm , respectively, whereas the second
 393 layer resistivity and third layer resistivity have lower uncertainty, i.e., 17.71 Ωm and 0.03 Ωm ,
 394 respectively.

395 **Table 1** True model, search range, and inverted layer parameters by hybrid wPSOGSA, GSA, and
 396 PSO for three-layer with different noise (0 %, 10 %, and 20 %) synthetic MT apparent resistivity
 397 and apparent phase data.

Layer parameters		ρ_1 (Ωm)	ρ_2 (Ωm)	ρ_3 (Ωm)	h_1 (m)	h_2 (m)
True model		30000	5000	1000	15000	18000
Search Range		5000 - 50000	1000 - 10000	50 - 5000	5000 - 25000	10000- 25000
(Shaw & Srivastava, 2007) 2.0 % Gaussian random noise	PSO	26981.80	6230.30	1011.70	13090	19720
	GA	40800	10000	1010	6210	25000
	RR	43424.40	3097.10	980.70	17010.00	16960.00
0 % noisy data	PSO	27463.86	4664.57	999.48	16112.66	17080.01
	GSA	32017.78	4721.69	1004.05	16195.26	17928.07
	wPSOGSA	30243.42	5007.04	1000.02	14969.33	18029.76
10 % noisy data	PSO	19861.54	7659.73	1022.19	15971.66	14774.31
	GSA	27538.91	6534.61	1018.04	14117.82	17408.14
	wPSOGSA	27589.85	6043.87	998.99	14902.89	18221.87

	GSA	28823.57	5825.19	1089.65	16861.84	20795.48
	wPSOGSA	29208.75	5282.77	1055.09	16573.22	18398.94

398

399 Table 1 shows the inverted layer parameters using wPSOGSA, GSA, and PSO for noise-
 400 free and noisy synthetic MT data based on posterior Bayesian PDF, as well as the actual model

401 and the search range. In addition, layered properties of synthetic data corrupted with 10 % and 20
 402 % random noise are compared and statistically analyzed. Our findings, as shown in Table 1, were
 403 compared to those obtained using the Genetic Algorithm (GA), Ridge Regression (RR), and PSO
 404 by (Shaw and Srivastava, 2007)), which consistently outperforms GA and RR is closer to the
 405 genuine model.

406
 407 **Figure 6** Histogram of selected models for misfit error below a defined threshold error of
 408 wPSOGSA.

409 Mean value of the accepted model parameters (30243.42 ± 471.26 , 5007.04 ± 39.59 ,
 410 1000.02 ± 0.064 , 14969.33 ± 136.82 , 18029.76 ± 114.90) with high uncertainty of the parameters (1.5
 411 %, 0.78 %, 0.0064 %, 0.91 % and 0.63 %). On the basis of low posterior PDF and high uncertainty,
 412 we have taken (ρ_1) and (h_1) for the exercise to show the models are not biased to the selected
 413 models.

414 As well as based on the histograms (see Fig. 6), posterior PDF and uncertainty of the
 415 inverted layer parameters resistivity (ρ_1) and thickness (h_1) for the three-layered synthetic MT
 416 data have been taken to depict the global solution using presented algorithm. Here we prepared

417 the cross-plots of ρ_1 versus h_1 using (a) wPSOGSA, (b) PSO, and (c) GSA, showing all accepted
 418 models (red circle), selected models with misfit error less than a threshold error of 10^{-4} (magenta
 419 circle), models of a PDF greater than 95 % (blue circle), models of a PDF greater than 75 % (green
 420 circle), models of a PDF greater than 68.27 % (yellow circle), and mean model, i.e., model
 421 parameters which having a PDF greater than 68.27 % (black asterisk) as shown in Fig. 7. It is
 422 noticed that all inverted results give the global solution which has a good agreement with the true
 423 model, whereas wPSOGSA gives the more accurate results than the other two algorithms PSO and
 424 GSA as shown in Table 2.

425

426 **Figure 7** Cross-plots of thickness and resistivity of first layer for the three-layered synthetic
 427 resistivity model using (a) wPSOGSA, (b) PSO, and (c) GSA, displaying all accepted models (red
 428 circle), selected models with misfit error less than a threshold error (magenta circle), models (pdf
 429 > 95 % CI, blue circle), models (pdf > 75 % CI, green circle), models (pdf > 68.27 % CI, yellow

430 circle), and mean model i.e. model parameters which having a PDF greater than 68.27 % (black
431 asterisk).

432

433 **3.1.2 Sensitivity, correlation matrix, and model parameters**

434 The accepted models, which have posterior PDF value within 68.27 % CI, are used to calculate
435 the correlation matrix. This correlation matrix gives the relationship among model parameters.
436 Thus, the lesser correlation value gives weak relation among the parameters and vice versa. The
437 correlation matrix of PSO, GSA, and wPSOGSA was examined on one set of synthetic data, as
438 shown in Fig. 8, Fig. 9 and Fig. 10, demonstrating the sensitivity among inverted model
439 parameters. The value of correlation matrix, 1.0 indicates that the two parameters are strongly
440 correlated.

441 Figure 8 shows that first layer resistivity is correlated highly positively with a first-layer
442 thickness (0.97) and second layer thickness (0.98), while the second layer resistivity (-0.99) and
443 third layer resistivity (-0.81) are substantially negative connected. Second layer resistivity is
444 correlated with the third layer resistivity (0.87) which has a significant positive relationship; while
445 second layer resistivity has a significant negative correlation with the first layer thickness (-0.99)
446 and the second layer thickness (-1.00). First layer thickness (-0.92) and second layer thickness (-
447 0.90) are very negatively associated with third layer resistivity, while first layer thickness is
448 extremely positively correlated with a second layer thickness (0.99).

449 Figure 9 indicates that first layer resistivity is highly associated with a second layer
450 thickness (1.00) and weakly with second layer resistivity (-1.00), third layer resistivity (-1.00),
451 and first layer thickness (-1.00). Second layer resistivity (-1) is highly linked with a second layer
452 thickness (-1.00), while third layer resistivity (1.00) and first layer thickness are strongly
453 correlated (1.00). Third layer resistivity has a highly positive correlation with a first-layer
454 thickness (1.00) and a strong negative correlation with a second layer thickness (-1.00), whereas
455 first layer thickness has a significant negative correlation with a second layer thickness (-1.00).

456

457 **Figure 8** Correlation matrix calculated from PSO inverted model using a three-layer noise-free
 458 synthetic MT apparent resistivity and apparent phase data.

459

460 **Figure 9** Correlation matrix calculated from GSA inverted model using a three-layer noise-free
 461 synthetic MT apparent resistivity and apparent phase data.

462 Figure 10 shows the correlation matrix of wPSOGSA. The analyses reveal that the first
 463 layer resistivity is strongly negative with the second layer resistivity, substantially negative (-0.92)
 464 with the third layer resistivity, weakly positive (0.30) with the first layer thickness, and

465 considerably (0.63) with the second layer thickness. Second layer resistivity is slightly positive
 466 (0.31) when compared to third layer resistivity (0.43) but substantially negative when compared
 467 to first layer thickness. Third layer resistivity has a slightly negative correlation (-0.23) with first
 468 layer thickness, but a moderately negative correlation (-0.71) with second layer thickness and first
 469 layer thickness has a negative correlation (-0.71). Thus, the conclusion can be made that the layer
 470 parameters are independent of others, so changing one will have no effect on the other compared
 471 to the result obtained via PSO and GSA algorithms.

472
 473 **Figure 10** Correlation matrix calculated from wPSOGSA inverted model using a three-layer
 474 noise-free synthetic MT apparent resistivity and apparent phase data.

475
 476 **3.1.3 Stability analysis**

477 We used two different search ranges for stability evaluation of proposed wPSOGSA algorithms
 478 and executed the algorithms over three layers of synthetic MT data. One of which is expanded,
 479 and the other is contracted by 10 % of the initial search range. We infer from three layers of
 480 synthetic data, results fluctuate by approximately 3 % from the true value when the search range

481 is changed. This variation is about 10 % on average for synthetic data corrupted with 30 % random
 482 noise, as shown in Table 2.

483 **Table 2** Stability analysis of a hybrid algorithm for three layers of synthetic data.

Layer parameters		ρ_1 (Ωm)	ρ_2 (Ωm)	ρ_3 (Ωm)	h_1 (m)	h_2 (m)
Search Range		5000- 50000	1000- 10000	50-5000	5000- 25000	10000- 25000
Search Range - Case 1		4500- 55000	900- 11000	45-5500	4500- 27500	9000- 27500
wPSOGSA inverted model	0 %	31092.47	5085.79	1000.14	14700.83	18251.85
	30 %	30113.82	5016.75	1137.05	15880.95	23970.22
Search Range - Case 2		5500- 45000	1100- 9000	55-4500	5500- 22500	11000- 22500
wPSOGSA inverted model	0 %	29078.26	4922.85	999.91	15273.25	17767.45
	30 %	27815.97	5464.88	1156.46	17398.41	18119.61

484

485 3.2 Application to synthetic MT data-Four layers case

486 For the second example of the synthetic data, a typical four-layer HK-type of earth model to
 487 analyse the performance of the present algorithm with Improved Differential Evolution (IDE)
 488 results obtained by Xiong et al. (2018). Analysis over noisy synthetic data is done by corrupting
 489 synthetic data with 10 % and 20 % Gaussian random noise to mimic the real field data because
 490 different types of noises influence apparent resistivity data. Following that, all three optimization
 491 methods are run using the noisy synthetic data. As the misfit error increases with the noise in the
 492 data, the Bayesian PDF of 68.27 % CI is calculated with respect to the threshold misfit error of
 493 0.01 and thus the mean model is calculated.

494 Enormous uncertainty is shown in the inverted results; hence, we calculated the mean
 495 model for 68.27 % CI using posterior Bayesian PDF to reduce the uncertainty and produce the
 496 global best solution. The optimized results obtained from the posterior PDF and the true model

497 are shown in Table 3. Figure 11 illustrate the inverted responses for PSO, GSA, and wPSOGSA
 498 are well-fitting as follows (a) observed and calculated apparent resistivity data, (b) observed and
 499 calculated apparent phase data, (c) 1-D depth model, and (d) convergence response of present
 500 algorithms. We have estimated the layer parameters for synthetic data corrupted with 20 % random
 501 noise for comparative analysis and found that the PSO, GSA, and wPSOGSA converge at
 502 iterations 96, 556, and 187 with associated errors 3.69, 4.04, and 3.69, respectively.

503
 504 **Figure 11** The inverted MT response by PSO (blue color), GSA (green color), and hybrid
 505 wPSOGSA (red color) with a true model (black color) over four-layer synthetic data as shown in
 506 (a) observed and calculated apparent resistivity curve, (b) observed and calculated apparent phase
 507 curve, (c) 1D depth inverted model and (d) convergence curve.

508 Additionally, the synthetic data corrupted with 10 % random noise is also used for the
 509 execution of inversion keeping the search range, a number of particles, and iterations same as
 510 before, and observed that the PSO, GSA, and wPSOGSA converge at iterations 151, 2 and 250
 511 with associated error 1.7609, 1.95 and 1.76 respectively. The posterior Bayesian PDF for threshold

512 data with 68.27 % CI is calculated similarly as a three-layer case to minimize the uncertainty in
 513 inverted results.

514 **Table 3** Comparison of the result obtained from improved Differential Evolution (IDE) and
 515 inverted results of PSO, GSA, and hybrid wPSOGSA obtained by using posterior PDF for four-
 516 layer synthetic apparent resistivity data with different Gauss noise levels (0 %, 10 %, and 20 %)
 517 and True model.

Layer parameters		ρ_1 (Ωm)	ρ_2 (Ωm)	ρ_3 (Ωm)	ρ_4 (Ωm)	h_1 (m)	h_2 (m)	h_3 (m)
True model		30.00	200.00	10.00	100.00	100.00	2000.00	3000.00
Search Range		25-35	100-250	5-15	50-150	50-200	1000-3000	2000-3500

518

519 3.2.1 Stability analysis

520 For the stability evaluation of presented algorithms over four layers of synthetic MT data, similar
 521 to the three-layer case, we used two different search ranges and executed the algorithms for 1000

522 iterations. The method exhibits good results with four layers of synthetic data and reveals minimal
 523 variation for noise-free data. For 30 % contaminated data, the variation is approximately 10 % and
 524 12 % in case 1 and case 2, respectively. The outputs don't change much across runs and provide
 525 consistent results, as shown in Table 4.

526 **Table 4** Stability analysis of a hybrid algorithm for four layers of MT synthetic data.

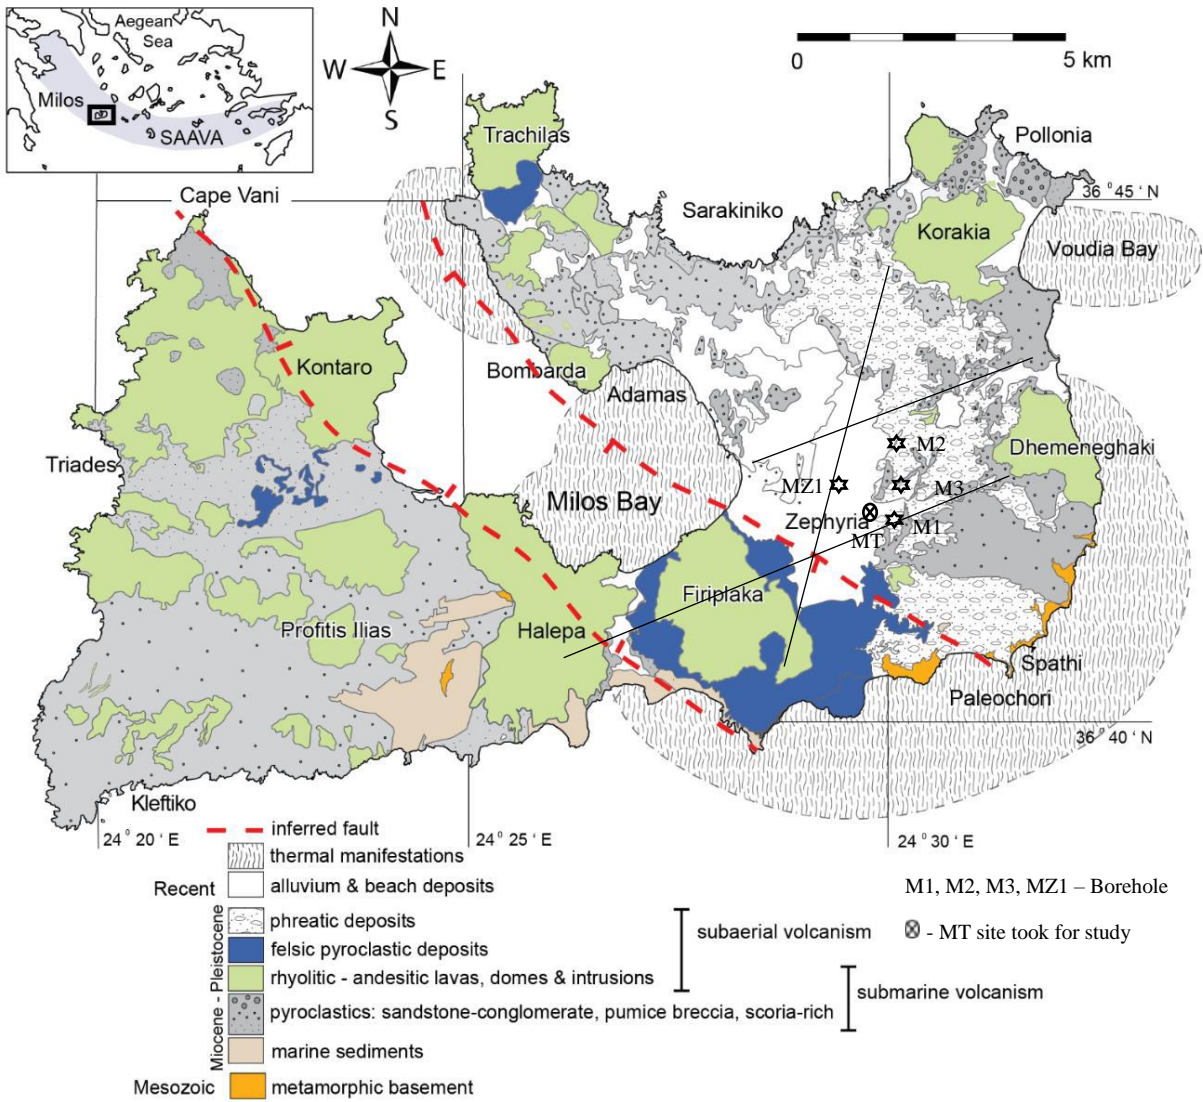

Layer parameters		ρ_1 (Ωm)	ρ_2 (Ωm)	ρ_3 (Ωm)	ρ_4 (Ωm)	h_1 (m)	h_2 (m)	h_3 (m)
Search Range		25-35	100- 250	5-15	50- 150	50- 200	1000- 3000	2000- 35000
Search Range-Case 1		27.50- 31.50	110- 225	5.50- 13.50	55- 135	55- 180	1100- 2700	2200- 3150

527

528 3.3 Application to field MT data-Island of Milos, Greece

529 In one-dimensional MT data for site G5 near borehole M2 (Hutton et al., 1989), as shown in Fig.
 530 12, the apparent resistivity and phase values are inverted using the wPSOGSA, PSO, and GSA,
 531 keeping the same set of controlling parameters as for noisy synthetic data, such as the swarm size,
 532 inertia weight (w), personal learning coefficient (c_1) and a global learning coefficient (c_2),
 533 descending coefficient (α), and the initial value of universal gravitational constant (G_0).

534

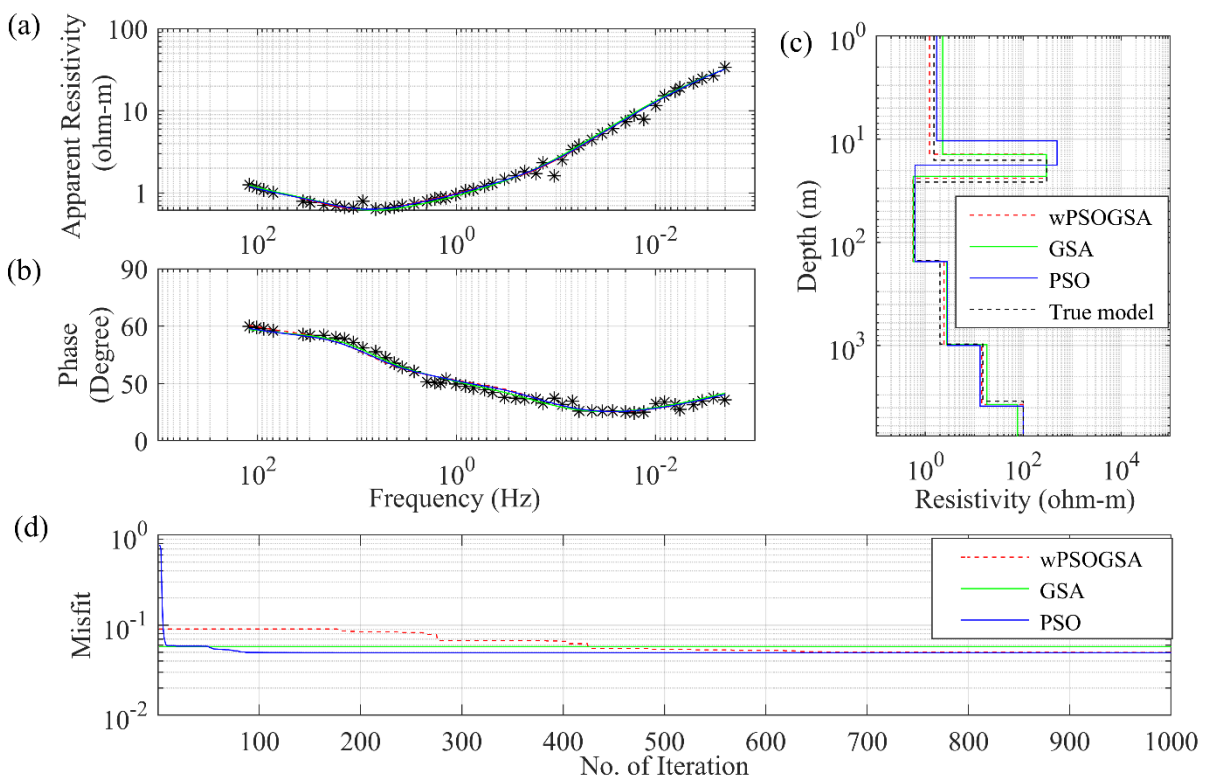

535 **Figure 12** The location of the MT site and geology of the Island of Milos, Greece (after (Stewart
 536 and McPhie, 2006)).

537 Figure 13 shows the calculated data and model parameters as (a) match between observed
 538 and computed apparent resistivity data, (b) match between observed and computed apparent phase
 539 data, and (c) 1D inverted model and (d) convergence response of wPSOGSA (red color), GSA
 540 (green color), and PSO (blue color) along with true model (black color). In subfigure Fig. 13(c)
 541 depicts alluvium deposits with a resistivity of $1.0 \Omega\text{m}$ with 15 m thickness as the top layer, and
 542 volcanic deposits with a resistivity of $300 \Omega\text{m}$ and 10 m thickness lie beneath the alluvium
 543 deposits. A very high conducting layer of resistivity less than $1.0 \Omega\text{m}$ is estimated, equivalent to
 544 the green lahar under the high resistivity volcanic deposits. The next layer below, with higher

545 resistivity, corresponds to the crystalline foundation. In the geothermal zone's depths, the
 546 resistivity drops again. The resistivity in the depth range of about 1000 m, which is similar to
 547 earlier studies, was explored, and the findings of the proposed algorithm discovered to be in good
 548 agreement with model developed by Dawes in Hutton et al. (1989).

549 In subfigure Fig. 13(d) reveals that the algorithms converge at iterations 218, 1, and 425
 550 with corresponding errors of 0.0494, 0.0518, and 0.0493 for PSO, GSA, and wPSOGSA,
 551 respectively. The hybrid algorithm has the least error between observed and computed data. The
 552 algorithms are executed for 1000 iterations and 10000 models, and findings are compared with
 553 available stratigraphy, and the result is derived using the Monte-Carlo technique by Hutton et al.
 554 (1989). After examining our optimized effects from Fig. 13 and Table 5, hybrid wPSOGSA
 555 outperformed PSO and GSA.

556
 557 **Figure 13** The inverted MT response by PSO (blue color), GSA (green color), and hybrid
 558 wPSOGSA (red color) with a true model (black color) over the geothermal area, Island of Milos,
 559 Greece, as shown in (a) observed and calculated apparent resistivity curve, (b) observed and
 560 calculated apparent phase curve, (c) 1D depth inverted model and (d) convergence curve.

561 **3.3.1 Bayesian analysis and uncertainty in model parameters**

562 A posterior Bayesian method determines the global model and related uncertainty. Figure 14
 563 shows another uncertainty study that examined the six-layered resistivity model over the
 564 geothermal field, Island of Milos, Greece, and found that the peak values of the posterior PDF for
 565 all model parameters are very nearer to the actual value of the layer parameters, providing less
 566 uncertainty. We have analyzed the wPSOGSA inverted results from the Fig. 14 and Table 5, and
 567 found that the first, second, third, fourth, fifth, and sixth layers' resistivity with uncertainty in
 568 associated layer parameters is $1.23 \pm 0.49 \Omega\text{m}$, $297.61 \pm 53.43 \Omega\text{m}$, $0.55 \pm 0.02 \Omega\text{m}$, $2.41 \pm 0.16 \Omega\text{m}$,
 569 $14.18 \pm 1.76 \Omega\text{m}$ and $99.92 \pm 0.37 \Omega\text{m}$. Similarly, the associated thicknesses with uncertainty are
 570 $14.51 \pm 1.35 \text{ m}$, $9.85 \pm 1.35 \text{ m}$, $127.39 \pm 6.01 \text{ m}$, $823.01 \pm 7.57 \text{ m}$ and $2750.88 \pm 63.07 \text{ m}$. Thus, the
 571 analysis suggests the lesser uncertainties in each layer's parameters except resistivity of the first
 572 and second layers.

573
 574 **Figure 14** Posterior Bayesian probability density function (PDF) with 68.27 % CI for
 575 wPSOGSA over a geothermal field, Island of Milos, Greece.

576 Table 5 compares optimized results obtained from all three presented algorithms based
 577 on posterior Bayesian PDF under 68.27 % CI condition. However, the 1D depth model inverted
 578 from wPSOGSA shows good agreement with the available borehole M-2 (Hutton et al., 1989).
 579 As a result, the hybrid algorithm is functioning better and the findings are encouraging.

580

584 3.3.2 Sensitivity, correlation matrix, and model parameters

585 Here, a similar study of the correlation matrix is carried out for field example from the Island of
 586 Milos, Greece using all accepted models, which have posterior PDF values within 68.27 % CI.
 587 The correlation matrix of PSO, GSA, and wPSOGSA was examined over the field MT data as
 588 shown in Fig. 15, Fig. 16 and Fig.17 demonstrating the sensitivity among inverted model
 589 parameters and found an almost similar correlation among the layer parameters for three-layer
 590 synthetic study. From correlation analyses, we noticed that the values are showing moderate and
 591 weak correlation among parameters in the wPSOGSA case, indicating that wPSOGSA is linearly
 592 independent of layer parameters. This indicates that the parameter is less affected by other layer
 593 parameters and resistivity curves. Whereas the correlation among layer parameters for field data
 594 using GSA and PSO is either strongly positive or strongly negative, which describes that the

595 parameters are dependent on each other. Thus a change in one parameter affects the other, and
 596 also apparent resistivity curve is very much involved.

607

608

609 **3.4 Application to field MT data-Newcastleton, Southern upland, Scotland**

610 Another field example of MT data was picked to illustrate our technique from Newcastleton
611 (2.796° W, 55.196° N in Geographic coordinates), Southern Uplands of Scotland. The Southern
612 Uplands are isolated from the Midland Valley by the Southern Uplands fault. The location of the
613 MT site and the geology of the study area are shown in Fig. 18.

614 During nine days, in the frequency range of 0.1 Hz to 0.0001 Hz, the variations of the
615 magnetic and telluric fields concerning the time at four sites along a line perpendicular to the
616 anomaly's strike were recorded, keeping a high signal to noise ratio where the anisotropy ratios
617 are so near to one and the skew factor is less than 0.1 for the majority of periods. Due to low
618 anisotropy ratios and skew factor, the resistivity distribution under this location is one-dimensional
619 (Jones and Hutton, 1979). Here one set of MT data is inverted using PSO, GSA, and wPSOGSA
620 to obtain the best fitting apparent resistivity curve, apparent phase curve, and 1D depth model as
621 shown in subfigures Fig. 19(a), Fig. 19(b), and Fig. 19(c), respectively. Figure 19 shows a realistic
622 one-dimensional resistivity variation with a phase response ranging from 60° at 100 seconds to
623 35° at 1000 seconds, which can only be obtained by establishing a conducting zone at lower
624 crustal/upper mantle levels (Jones and Hutton, 1979).

625 The execution time for wPSOGSA (33 seconds) is the least as compared to GSA (34
626 seconds) and PSO (53 seconds). The convergence iterations of PSO, GSA, and wPSOGSA are 79,
627 101, and 65, and its associated misfit errors are 3.79, 4.72, and 3.70, respectively.

628 The inverted MT model is illustrated in subfigure Fig. 19(c), which depicts two low
629 conductive zones at a depth of 21 km and 400 km. The first conductive layer (70 Ωm) with a
630 thickness of 28 km is underlain by a high resistive top layer of thickness of 21 km, and the second
631 very high conductive layer (less than 1.0 Ωm) at a depth of 400 km is underlain by high resistive
632 layer (550 Ωm) of thickness 351 km. Thus, the last layer of a very high conductive zone (i.e.,
633 resistivity less than 1.0 Ωm) as a lower crust/upper mantle conductor at a depth of 400 km is
634 estimated. At 400 m depths, a conducting zone meets both the amplitude and phase long period

635 responses. This explanation is directly equivalent to accepted models derived from Monte-Carlo
 636 models for the structure underlying the Southern Uplands.

637

648

649 **4.0 Discussions**

650 The analysis on the two synthetic MT datasets shows that the proposed algorithm work very well
 651 and provide encouraging well fitted calculated apparent resistivity and phase data with the
 652 observed data. Also from the study, it is noted that the proposed algorithm is less sensitive to the
 653 search range and the constraints used in this algorithm. And the comparison of the model
 654 parameters show that the output from the proposed algorithm is very precise to the true model and
 655 faster than the individual algorithms and the other algorithms used in the previous papers.

656

659

660 A research conducted by Hutton et al. (1989), compare various techniques, including
 661 Parker H+, Dawes (a combined Monte Carlo/Hedgehog approach developed by Dawes), Jupp-
 662 Vozoff, Fischer, and Parker D+ inversions, to interpret the subsurface geology of the Island of
 663 Milos, Greece. Among these techniques, the Dawes algorithm proved to be the most effective in

664 identifying a reservoir interface at the borehole's depth. Consequently, these methods were utilized
665 to compile 1-D models along several traverses. All three models, Parker H+, Parker D+, and
666 Dawes, indicate the presence of a resistivity boundary at a depth of approximately 1000 m (Hutton
667 et al., 1989), where the geothermal reservoir has been detected. The research findings through
668 proposed algorithm reveal that the resistivity of the crystalline basement beneath the geothermal
669 site is abnormally low ($< 20 \Omega\text{m}$) in the uppermost portion and remains below $50 \Omega\text{m}$ at depths of
670 at least 10 km.

671 The subfigure in Fig. 19(c) presents the inverted MT model of the Southern upland,
672 Scotland, displaying two zones of low conductivity at depths of 21 km and 400 km. Contrary to
673 the findings of Jain and Wilson (1967), there is a strong evidence suggesting that the conducting
674 zone ($70 \Omega\text{m}$) beneath the Southern Uplands exists at a depth exceeding 20 km. Furthermore, there
675 is a second layer of extremely high conductivity (representing lower crust/upper mantle of less
676 than $1.0 \Omega\text{m}$) at a depth of 400 km, which is underlain by a highly resistive layer ($550 \Omega\text{m}$)
677 spanning a thickness of 351 km. At a depth of 400 m, this conducting zone shows a direct
678 alignment with both the amplitude and phase responses of long period measurements, which can
679 be notice in the model derived from Monte-Carlo simulations of the structure underlying the
680 Southern Uplands (see Fig. 19). The results from proposed algorithm as well as from PSO and
681 GSA (see Fig. 19), demonstrate the presence of a highly conductive layer at depths exceeding 20
682 km and 400 km, corroborating with the findings of (Jones and Hutton, 1979).

689

690 **5.0 Conclusions**

691 The study presented the wPSOGSA algorithm along with PSO and GSA to evaluate their efficacy
692 and applicability to the MT data, which narrates the appraisal of 1D resistivity models from
693 apparent resistivity, apparent phase, and the frequency data sets. So, synthetic and field MT data
694 from various geological terrains were used to demonstrate the relevance of these methods, which
695 are further carried out by applying multiple runs, generating a large number of models that fit the
696 apparent resistivity and apparent phase curves. Furthermore, these best-fitting models within a
697 specified range are then chosen for statistical analysis. The statistical analysis includes posterior
698 PDF based on the Bayesian approach with 68.27 % CI, correlation matrix, and stability analysis
699 are used to understand the accuracy of the mean model and its uncertainty. However, the solution
700 from the posterior PDF based on the Bayesian of wPSOGSA is better than GSA and PSO,
701 explaining the reliability of the proposed inversion algorithm. In general, conventional techniques
702 can effectively resolve the model in random noise, but they can miscarry in methodical error or
703 inappropriate models, also, the performance of the proposed algorithms on field datasets has been
704 analyzed based on the mean model, uncertainty, correlation and stability of layered earth models,
705 and found that the results obtained from wPSOGSA are reliable, stable, and more accurate than
706 the available results, that are well adapted to borehole lithology.
